STAD29: Statistics for the Life and Social Sciences

Lecture notes

Section 1

Course Outline

Course and instructor

- Lecture: Wednesday 14:00-16:00 in HW 215. Optional computer lab Monday 16:00-17:00 in BV 498.
- Instructor: Ken Butler
- Office: IC 471.
- E-mail: butler@utsc.utoronto.ca
- Office hours: Monday 11:00-13:00. I am often around otherwise. See if I'm in. Or make an appointment. E-mail always good.
- Course website: link.
- Using Quercus for assignments/grades only; using website for everything else.

Texts

- There is no official text for this course.
- You may find "R for Data Science", link helpful for R background.
- I will refer frequently to my book of Problems and Solutions in Applied Statistics (PASIAS), link.
- Both of these resources are and will remain free.

Programs, prerequisites and exclusions

- Prerequisites:
- For undergrads: STAC32. Not negotiable.
- For grad students, a first course in statistics, and some training in regression and ANOVA. The less you know, the more you'll have to catch up!
- This course is a required part of Applied Statistics minor.
- Exclusions: this course is not for Math/Statistics/CS
 majors/minors. It is for students in other fields who wish to learn
 some more advanced statistical methods. The exclusions in the
 Calendar reflect this.
- If you are in one of those programs, you won't get program credit for this course, or for any future STA courses you take.

Computing

- Computing: big part of the course, not optional. You will need to demonstrate that you can use R to analyze data, and can critically interpret the output.
- For grad students who have not come through STAC32, I am happy to offer extra help to get you up to speed.

Assessment 1/2

 Grading: (2 hour) midterm, (3 hour) final exam. Assignments most weeks, due Tuesday at 11:59pm. Graduate students (STA 1007) also required to complete a project using one or more of the techniques learned in class, on a dataset from their field of study. Projects due on the last day of classes.

Assessment:

	STAD29	STA 1007
Assignments	20%	20%
Midterm exam	30%	20%
Project	-	20%
Final exam	50%	40%

Assessment 2/2

- Assessments missed with documentation will cause a re-weighting of other assessments of same type. No make-ups.
- You must pass the final exam to guarantee passing the course. If you fail the final exam but would otherwise have passed the course, you receive a grade of 45.

Plagiarism

- **This link** defines academic offences at this university. Read it. You are bound by it.
- Plagiarism defined (at the end) as
 The wrongful appropriation and purloining, and publication as
 one's own, of the ideas, or the expression of the ideas ... of another.
- The code and explanations that you write and hand in must be yours and yours alone.
- When you hand in work, it is implied that it is your work. Handing in work, with your name on it, that was actually done by someone else is an academic offence.
- If I am suspicious that anyone's work is plagiarized, I will take action.

Getting help

- The English Language Development Centre supports all students in developing better Academic English and critical thinking skills needed in academic communication. Make use of the personalized support in academic writing skills development. Details and sign-up information: link.
- Students with diverse learning styles and needs are welcome in this course. In particular, if you have a disability/health consideration that may require accommodations, please feel free to approach the AccessAbility Services Office as soon as possible. I will work with you and AccessAbility Services to ensure you can achieve your learning goals in this course. Enquiries are confidential. The UTSC AccessAbility Services staff are available by appointment to assess specific needs, provide referrals and arrange appropriate accommodations: (416) 287-7560 or by e-mail: ability@utsc.utoronto.ca.

Course material

- Regression-like things
 - review of (multiple) regression
 - logistic regression (including multi-category responses)
 - survival analysis
- ANOVA-like things
 - more ANOVA
 - multivariate ANOVA
 - repeated measures
- Multivariate methods
 - discriminant analysis
 - cluster analysis
 - multidimensional scaling
 - principal components
 - factor analysis
- Miscellanea
 - time series
 - multiway frequency tables

Section 2

Review of (multiple) regression

Regression

- Use regression when one variable is an outcome (response, y).
- See if/how response depends on other variable(s), explanatory, x_1, x_2, \ldots
- Can have one or more than one explanatory variable, but always one response.
- Assumes a straight-line relationship between response and explanatory.
- Ask:
 - is there a relationship between y and x's, and if so, which ones?
 - what does the relationship look like?

Packages

```
library(MASS) # for Box-Cox, later
library(tidyverse)
library(broom)
```

A regression with one *x*

13 children, measure average total sleep time (ATST, mins) and age (years) for each. See if ATST depends on age. Data in sleep.txt, ATST then age. Read in data:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/sleep.txt"
sleep <- read_delim(my_url, " ")

## Parsed with column specification:
## cols(
## atst = col_double(),
## age = col double()</pre>
```

)

Check data

summary(sleep)

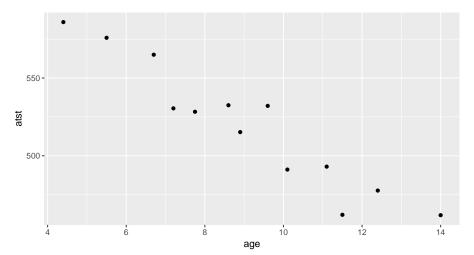

atst

##

```
age
##
   Min. :461.8
                  Min. : 4.400
##
   1st Qu.:491.1
                  1st Qu.: 7.200
   Median :528.3
##
                  Median: 8.900
   Mean :519.3
##
                  Mean : 9.058
##
   3rd Qu.:532.5
                  3rd Qu.:11.100
##
   Max. :586.0
                  Max. :14.000
```

Make scatter plot of ATST (response) vs. age (explanatory) using code overleaf:

The scatterplot

Correlation

• Measures how well a straight line fits the data:

```
with(sleep, cor(atst, age))
```

```
## [1] -0.9515469
```

- ullet 1 is perfect upward trend, -1 is perfect downward trend, 0 is no trend.
- This one close to perfect downward trend.
- Can do correlations of all pairs of variables:

cor(sleep)

```
## atst age
## atst 1.0000000 -0.9515469
## age -0.9515469 1.0000000
```

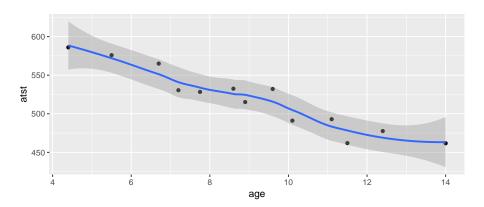

Lowess curve

- Sometimes nice to guide the eye: is the trend straight, or not?
- Idea: *lowess curve*. "Locally weighted least squares", not affected by outliers, not constrained to be linear.
- Lowess is a *guide*: even if straight line appropriate, may wiggle/bend a little. Looking for *serious* problems with linearity.
- Add lowess curve to plot using geom_smooth:

Plot with lowess curve

```
ggplot(sleep, aes(x = age, y = atst)) + geom_point() +
  geom_smooth()
```

$geom_smooth()$ using method = 'loess' and formula 'y ~ x'

The regression

Scatterplot shows no obvious curve, and a pretty clear downward trend. So we can run the regression:

```
sleep.1 <- lm(atst ~ age, data = sleep)</pre>
```

The output xxx

summary(sleep.1)

```
##
## Call:
## lm(formula = atst ~ age, data = sleep)
##
## Residuals:
      Min 10 Median 30
##
                                    Max
## -23.011 -9.365 2.372 6.770 20.411
##
## Coefficients:
##
              Estimate Std. Error t value Pr(>|t|)
## (Intercept) 646.483 12.918 50.05 2.49e-14 ***
## age
              -14.041 1.368 -10.26 5.70e-07 ***
## ---
## Signif. codes:
## 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 13.15 on 11 degrees of freedom
## Multiple R-squared: 0.9054, Adjusted R-squared: 0.8968
## F-statistic: 105.3 on 1 and 11 DF, p-value: 5.7e-07
```

Conclusions

- The relationship appears to be a straight line, with a downward trend.
- F-tests for model as a whole and t-test for slope (same) both confirm this (P-value $5.7 \times 10^{-7} = 0.00000057$).
- \bullet Slope is -14, so a 1-year increase in age goes with a 14-minute decrease in ATST on average.
- R-squared is correlation squared (when one x anyway), between 0 and 1 (1 good, 0 bad).
- Here R-squared is 0.9054, pleasantly high.

Doing things with the regression output

- Output from regression (and eg. t-test) is all right to look at, but hard to extract and re-use information from.
- Package broom extracts info from model output in way that can be used in pipe (later):

```
tidy(sleep.1)
```

```
## # A tibble: 2 x 5
##
    term
                estimate std.error statistic p.value
    <chr>
                   <dbl>
                             <dbl>
                                      <dbl>
                                               <dbl>
##
## 1 (Intercept)
                   646. 12.9
                                       50.0 2.49e-14
                             1.37
                                      -10.3 5.70e- 7
  2 age
                   -14.0
```

also one-line summary of model:

glance(sleep.1)

Broom part 2

CI for mean response and prediction intervals

Once useful regression exists, use it for prediction:

- To get a single number for prediction at a given x, substitute into regression equation, eg. age 10: predicted ATST is 646.48-14.04(10)=506 minutes.
- To express uncertainty of this prediction:
- CI for mean response expresses uncertainty about mean ATST for all children aged 10, based on data.
- Prediction interval expresses uncertainty about predicted ATST for a new child aged 10 whose ATST not known. More uncertain.
- Also do above for a child aged 5.

Intervals

Make new data frame with these values for age

```
my.age <- c(10, 5)
ages.new <- tibble(age = my.age)
ages.new

## # A tibble: 2 x 1</pre>
```

```
## age
## <dbl>
## 1 10
## 2 5
```

• Feed into predict:

```
pc <- predict(sleep.1, ages.new, interval = "c")
pp <- predict(sleep.1, ages.new, interval = "p")</pre>
```

The intervals

Confidence intervals for mean response:

```
cbind(ages.new, pc)
```

```
## age fit lwr upr
## 1 10 506.0729 497.5574 514.5883
## 2 5 576.2781 561.6578 590.8984
```

Prediction intervals for new response:

```
cbind(ages.new, pp)
```

```
## age fit lwr upr
## 1 10 506.0729 475.8982 536.2475
## 2 5 576.2781 543.8474 608.7088
```

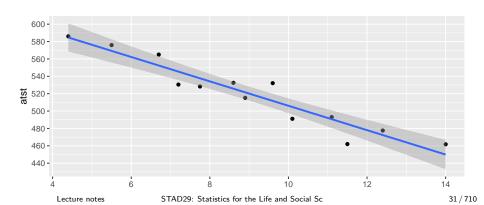

Comments

- Age 10 closer to centre of data, so intervals are both narrower than those for age 5.
- Prediction intervals bigger than CI for mean (additional uncertainty).
- Technical note: output from predict is R matrix, not data frame, so Tidyverse bind_cols does not work. Use base R cbind.

That grey envelope

Marks confidence interval for mean for all x: xxx

```
ggplot(sleep, aes(x = age, y = atst)) + geom_point() +
geom_smooth(method = "lm") +
scale_y_continuous(breaks = seq(420, 600, 20))
```

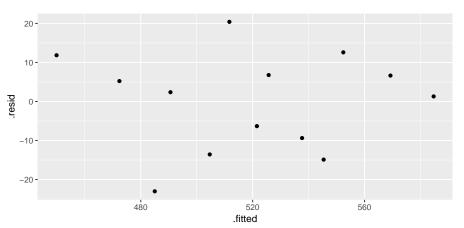

Diagnostics

How to tell whether a straight-line regression is appropriate?

- Before: check scatterplot for straight trend.
- After: plot residuals (observed minus predicted response) against predicted values. Aim: a plot with no pattern.

Residual plot xxx

Not much pattern here — regression appropriate.

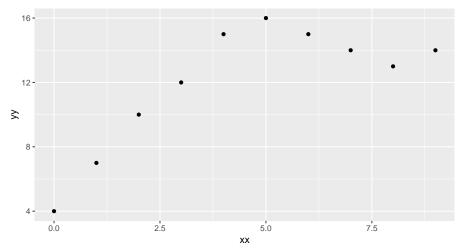

An inappropriate regression

Different data:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/curvy.txt"
curvy <- read_delim(my_url, " ")
## Parsed with column specification:
## parset</pre>
```

```
## cols(
## xx = col_double(),
## yy = col_double()
## )
```

Scatterplot

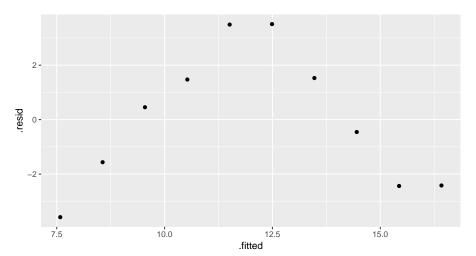

Regression line, anyway

```
curvy.1 \leftarrow lm(yy \sim xx, data = curvy)
summary(curvy.1)
##
## Call:
## lm(formula = yy ~ xx, data = curvy)
##
## Residuals:
##
     Min 1Q Median 3Q
                                Max
## -3.582 -2.204 0.000 1.514 3.509
##
## Coefficients:
##
              Estimate Std. Error t value Pr(>|t|)
## (Intercept) 7.5818 1.5616 4.855 0.00126 **
          0.9818 0.2925 3.356 0.00998 **
## xx
## ---
## Signif. codes:
## 0 '*** 0.001 '** 0.01 '* 0.05 '. ' 0.1 ' ' 1
##
## Residual standard error: 2.657 on 8 degrees of freedom
## Multiple R-squared: 0.5848, Adjusted R-squared: 0.5329
## F-statistic: 11.27 on 1 and 8 DF, p-value: 0.009984
```

Residual plot

ggplot(curvy.1, aes(x = .fitted, y = .resid)) + geom_point()

No good: fixing it up

- Residual plot has *curve*: middle residuals positive, high and low ones negative. Bad.
- Fitting a curve would be better. Try this:

```
curvy.2 <- lm(yy ~ xx + I(xx^2), data = curvy)</pre>
```

- Adding xx-squared term, to allow for curve.
- Another way to do same thing: specify how model changes:

```
curvy.2a <- update(curvy.1, . ~ . + I(xx^2))</pre>
```

<chr> <dbl> <dbl>

Regression 2 xxx

A tibble: 3 x 5

```
tidy(curvy.2)
```

STAD29: Statistics for the Life and Social Sc

<dbl>

<dbl>

39 / 710

term estimate std.error statistic p.value

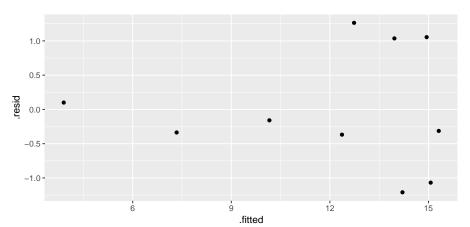

1 (Intercept) 3.9 0.773 5.04 0.00149

Comments

- xx-squared term definitely significant (P-value 0.000182), so need this curve to describe relationship.
- Adding squared term has made R-squared go up from 0.5848 to 0.9502: great improvement.
- This is a definite curve!

The residual plot now xxx

No problems any more:

Another way to handle curves

- Above, saw that changing x (adding x^2) was a way of handling curved relationships.
- Another way: change y (transformation).
- Can guess how to change y, or might be theory:
- example: relationship $y = ae^{bx}$ (exponential growth):
- take logs to get $\ln y = \ln a + bx$.
- ullet Taking logs has made relationship linear ($\ln y$ as response).
- Or, estimate transformation, using Box-Cox method.

Box-Cox

- Install package MASS via install.packages("MASS") (only need to do once)
- Every R session you want to use something in MASS, type library(MASS)

Some made-up data

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/madeup.csv"
madeup <- read_csv(my_url)</pre>
madeup
```

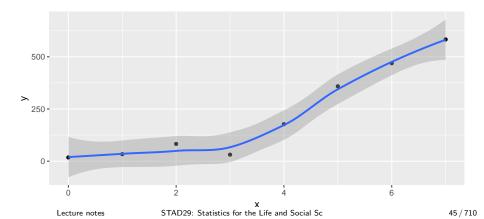

```
## # A tibble: 8 x 3
##
       row
                X
     <dbl> <dbl> <dbl>
##
## 1
                0 17.9
## 2
                1 33.6
         3
                2 82.7
## 3
                3 31.2
## 4
                4 177.
## 5
         5
         6
                5 359.
## 6
## 7
                6 469.
         8
                7 583.
## 8
```

Seems to be faster-than-linear growth, maybe exponential growth. STAD29: Statistics for the Life and Social Sc

Scatterplot: faster than linear growth xxx

```
ggplot(madeup, aes(x = x, y = y)) + geom_point() +
  geom_smooth()
```

```
## `geom_smooth()` using method = 'loess' and formula 'y ~ x'
```

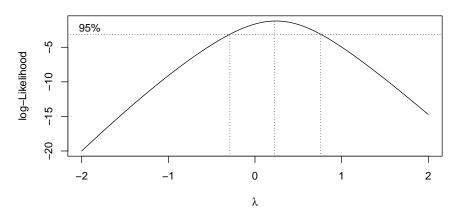

Running Box-Cox

- library(MASS) first.
- Feed boxcox a model formula with a squiggle in it, such as you would use for lm.
- Output: a graph (next page):

```
boxcox(y ~ x, data = madeup)
```

The Box-Cox output

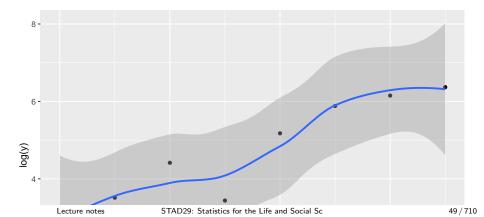

Comments

- λ (lambda) is the power by which you should transform y to get the relationship straight (straighter). Power 0 is "take logs"
- Middle dotted line marks best single value of λ (here about 0.1).
- Outer dotted lines mark 95% CI for λ , here -0.3 to 0.7, approx. (Rather uncertain about best transformation.)
- Any power transformation within the CI supported by data. In this case, $\log (\lambda = 0)$ and square root $(\lambda = 0.5)$ good, but no transformation $(\lambda = 1)$ not.
- Pick a "round-number" value of λ like 2, 1, 0.5, 0, -0.5, -1. Here 0 and 0.5 good values to pick.

Did transformation straighten things?

• Plot transformed y against x. Here, log: xxx

```
ggplot(madeup, aes(x = x, y = log(y))) + geom_point() +
  geom_smooth()
```

Regression with transformed y

```
xxx from here
```

```
madeup.1 \leftarrow lm(log(y) \sim x, data = madeup)
glance(madeup.1)
## # A tibble: 1 x 11
##
    r.squared adj.r.squared sigma statistic p.value
                                                        df
##
         <dbl>
                      <dbl> <dbl>
                                       <dbl> <dbl> <int>
## 1
        0.883
                       0.864 0.501 45.3 5.24e-4
## # ... with 5 more variables: logLik <dbl>, AIC <dbl>,
## #
      BIC <dbl>, deviance <dbl>, df.residual <int>
tidy(madeup.1)
```

R-squared now decently high.

Multiple regression

- What if more than one x? Extra issues:
 - Now one intercept and a slope for each x: how to interpret?
 - Which x-variables actually help to predict y?
 - Different interpretations of "global" F-test and individual t-tests.
 - R-squared no longer correlation squared, but still interpreted as "higher better".
 - In 1m line, add extra xs after ~.
 - Interpretation not so easy (and other problems that can occur).

Multiple regression example

Study of women and visits to health professionals, and how the number of visits might be related to other variables:

timedrs: number of visits to health professionals (over course of study)

phyheal: number of physical health problems

menheal: number of mental health problems

stress: result of questionnaire about number and type of life changes timedrs response, others explanatory.

The data xxx

```
my_url <-
  "http://www.utsc.utoronto.ca/~butler/d29/regressx.txt"
visits <- read delim(my url, " ")</pre>
## Parsed with column specification:
## cols(
##
     subjno = col_double(),
##
     timedrs = col_double(),
     phyheal = col_double(),
##
     menheal = col_double(),
##
```

stress = col_double()

##

)

Check data

visits

```
## # A tibble: 465 x 5
##
      subjno timedrs phyheal menheal stress
       <dbl>
                <dbl> <dbl>
                                   dbl>
##
                                           <dbl>
                               5
                                              265
##

```

The physical health and stress variables initely help to predict the number of visits, but with those in the model we don't need menheal. However, look at prediction of timedrs from menheal by itself:

Just menheal xxx

tidy(visits.2)

menheal by itself

- menheal by itself does significantly help to predict timedrs.
- But the R-sq is much less (6.5% vs. 22%).
- So other two variables do a better job of prediction.
- With those variables in the regression (phyheal and stress), don't need menheal as well.

Investigating via correlation

Leave out first column (subjno):

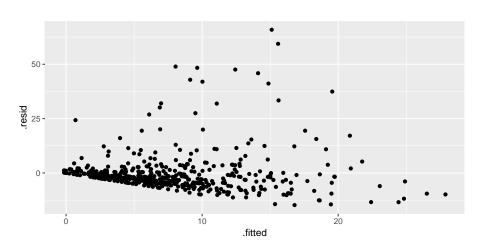

```
visits %>% select(-subjno) %>% cor()
```

```
## timedrs phyheal menheal stress
## timedrs 1.0000000 0.4395293 0.2555703 0.2865951
## phyheal 0.4395293 1.0000000 0.5049464 0.3055517
## menheal 0.2555703 0.5049464 1.0000000 0.3697911
## stress 0.2865951 0.3055517 0.3697911 1.0000000
```

- phyheal most strongly correlated with timedrs.
- Not much to choose between other two.
- But menheal has higher correlation with phyheal, so not as much to add to prediction as stress.
- Goes to show things more complicated in multiple regression.

Residual plot (from timedrs on all) xxx

ggplot(visits.1, aes(x = .fitted, y = .resid)) + geom_point()

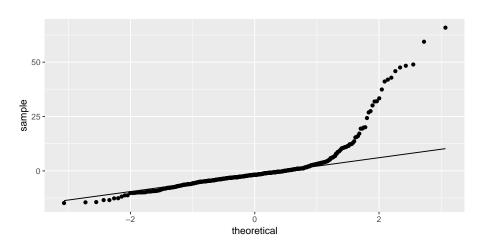

Comment xxx

Apparently random. But...

Normal quantile plot of residuals

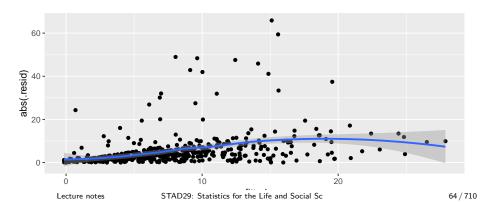

ggplot(visits.1, aes(sample = .resid)) + stat_qq() + stat_qq__

Absolute residuals

Is there trend in *size* of residuals (fan-out)? Plot *absolute value* of residual against fitted value: xxx

```
ggplot(visits.1, aes(x = .fitted, y = abs(.resid))) +
  geom_point() + geom_smooth()
```

Comments

- On the normal quantile plot:
 - highest (most positive) residuals are way too high
 - distribution of residuals skewed to right (not normal at all)
- On plot of absolute residuals:
 - size of residuals getting bigger as fitted values increase
 - predictions getting more variable as fitted values increase
 - that is, predictions getting less accurate as fitted values increase, but predictions should be equally accurate all way along.
- Both indicate problems with regression, of kind that transformation of response often fixes: that is, predict function of response timedrs instead of timedrs itself.

Fixing the problems

Lecture notes

- Residuals not normal (skewed right), increase in size with fitted value.
- Sometimes residuals are *very* positive: observed a *lot* larger than predicted.
- Try transforming response: use log or square root of response. (Note that response is *count*, often skewed to right.)
- Try regression again, with transformed response instead of original one.
- Then check residual plot to see that it is OK now.

```
visits.3 <- lm(log(timedrs + 1) ~ phyheal + menheal + stress,
  data = visits
```

- timedrs+1 because some timedrs values 0, can't take log of 0.
- Won't usually need to worry about this, but when response could be ative fix that before transformation STAD29: Statistics for the Life and Social Sc

Output

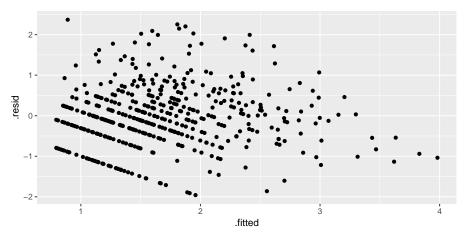

```
summary(visits.3)
##
## Call:
## lm(formula = log(timedrs + 1) ~ phyheal + menheal + stress, data = visits)
##

## phyheal 0.2019361 0.0173624 11.631 < 2e-16 ***
## menheal 0.0071442 0.0101335 0.705 0.481
## stress 0.0013158 0.0002837 4.638 4.58e-06 ***
## ---
## Signif. codes:
## 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 0.7625 on 461 degrees of freedom
## Multiple R-squared: 0.3682, Adjusted R-squared: 0.3641
## F-statistic: 89.56 on 3 and 461 DF. p-value: < 2.2e-16
```

Comments

- Model as a whole strongly significant again
- R-sq higher than before (37% vs. 22%) suggesting things more linear now
- Same conclusion re menheal: can take out of regression.
- Should look at residual plots (next pages). Have we fixed problems?

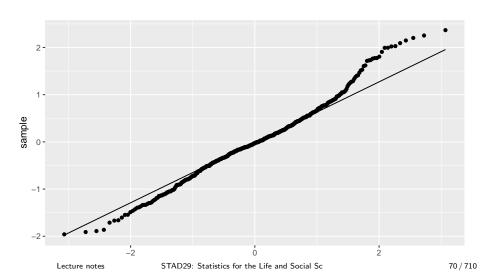

Residuals against fitted values

```
ggplot(visits.3, aes(x = .fitted, y = .resid)) +
  geom_point()
```

Normal quantile plot of residuals

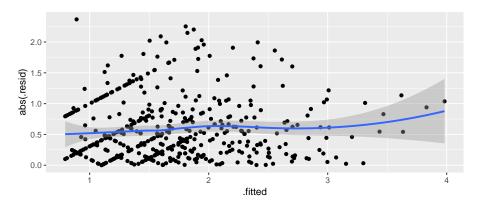

ggplot(visits.3, aes(sample = .resid)) + stat_qq() + stat_qq__

Absolute residuals against fitted

```
ggplot(visits.3, aes(x = .fitted, y = abs(.resid))) +
  geom_point() + geom_smooth()
```

$geom_smooth()$ using method = 'loess' and formula 'y ~ x

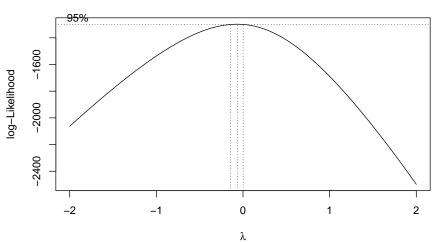

Comments

- Residuals vs. fitted looks a lot more random.
- Normal quantile plot looks a lot more normal (though still a little right-skewness)
- Absolute residuals: not so much trend (though still some).
- Not perfect, but much improved.

Box-Cox transformations

- Taking log of timedrs and having it work: lucky guess. How to find good transformation?
- Box-Cox again.
- Extra problem: some of timedrs values are 0, but Box-Cox expects all
 Note response for boxcox:
- boxcox(timedrs + 1 ~ phyheal + menheal + stress, data = visits

Try 1

Comments on try 1

- Best: λ just less than zero.
- Hard to see scale.
- Focus on λ in (-0.3, 0.1):

```
my.lambda <- seq(-0.3, 0.1, 0.01)
my.lambda
## [1] -0.30 -0.29 -0.28 -0.27 -0.26 -0.25 -0.24 -0.23 -
```

```
0.22

## [10] -0.21 -0.20 -0.19 -0.18 -0.17 -0.16 -0.15 -0.14 -
0.13

## [19] -0.12 -0.11 -0.10 -0.09 -0.08 -0.07 -0.06 -0.05 -
0.04

## [28] -0.03 -0.02 -0.01 0.00 0.01 0.02 0.03 0.04 0.05
```

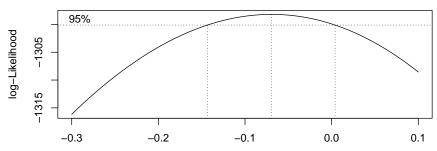

0.09 0.10

[37]

0.06 0.07 0.08

Try 2

```
boxcox(timedrs + 1 ~ phyheal + menheal + stress,
  lambda = my.lambda,
  data = visits
)
```

Comments

- Best: λ just about -0.07.
- CI for λ about (-0.14, 0.01).
- Only nearby round number: $\lambda = 0$, log transformation.
- So we made lucky guess with log before!

Testing more than one x at once

The t-tests test only whether one variable could be taken out of the regression you're looking at. To test significance of more than one variable at once, fit model with and without variables and use anova to compare fit of models: $\{$

```
visits.5 <- lm(log(timedrs + 1) ~ phyheal + menheal + stress, data = visits.6 <- lm(log(timedrs + 1) ~ stress, data = visits)
anova(visits.6, visits.5)

## Analysis of Variance Table
##
## Model 1: log(timedrs + 1) ~ stress
## Model 2: log(timedrs + 1) ~ phyheal + menheal + stress</pre>
```

Model 2: log(timedrs + 1) ~ pnyheal + menneal + str ## Res.Df RSS Df Sum of Sq F Pr(>F) ## 1 463 371.47 ## 2 461 268.01 2 103.46 88.984 < 2.2e-16 *** ## ---## Signif. codes: ## 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1

Results of tests

- Models don't fit equally well, so big one fits better.
- Or "taking both variables out makes the fit worse, so don't do it".
- ullet Taking out those x's is a mistake. Or putting them in is a good idea.

The punting data

Data set punting.txt contains 4 variables for 13 right-footed football kickers (punters): left leg and right leg strength (lbs), distance punted (ft), another variable called "fred". Predict punting distance from other variables:

left	right	punt	fred
170	170	162.50	171
130	140	144.0	136
170	180	174.50	174
160	160	163.50	161
150	170	192.0	159
150	150	171.75	151
180	170	162.0	174
110	110	104.83	111
110	120	105.67	114
120	130	117.58	126
140	120	140.25	129
130	140	150.17	136
150	160	165.17	154

STAD29: Statistics for the Life and Social Sc.

Comments

- Overall regression strongly significant, R-sq high.
- None of the x's significant! Why?
- *t*-tests only say that you could take any one of the *x*'s out without damaging the fit; doesn't matter which one.
- Explanation: look at correlations.

The correlations

cor(punting)

```
## left right punt fred
## left 1.0000000 0.8957224 0.8117368 0.9722632
## right 0.8957224 1.0000000 0.8805469 0.9728784
## punt 0.8117368 0.8805469 1.0000000 0.8679507
## fred 0.9722632 0.9728784 0.8679507 1.0000000
```

- All correlations are high: x's with punt (good) and with each other (bad, at least confusing).
- What to do? Probably do just as well to pick one variable, say right since kickers are right-footed.

Just right

```
punting.2 <- lm(punt ~ right, data = punting)
anova(punting.2, punting.1)</pre>
```

```

```

But...

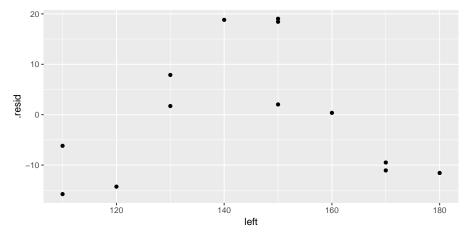

- Maybe we got the form of the relationship with left wrong.
- Check: plot *residuals* from previous regression (without left) against left.
- Residuals here are "punting distance adjusted for right leg strength".
- If there is some kind of relationship with left, we should include in model.
- Plot of residuals against original variable: augment from broom.

Augmenting punting.2

```
punting.2 %>% augment(punting) -> punting.2.aug
punting.2.aug %>% slice(1:8)
## # A tibble: 8 x 11
##
     left right punt fred .fitted .se.fit .resid

      .std.resid <dbl>
```

Residuals against left

```
ggplot(punting.2.aug, aes(x = left, y = .resid)) +
  geom_point()
```

Comments

- There is a curved relationship with left.
- We should add left-squared to the regression (and therefore put left back in when we do that):

```
punting.3 <- lm(punt ~ left + I(left^2) + right,
  data = punting
)</pre>
```

Regression with left-squared

```
summary(punting.3)
##

## 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
##
## Residual standard error: 7.931 on 9 degrees of freedom
## Multiple R-squared: 0.9352, Adjusted R-squared: 0.9136
## F-statistic: 43.3 on 3 and 9 DF. p-value: 1.13e-05
```

Comments

- This was initely a good idea (R-squared has clearly increased).
- We would never have seen it without plotting residuals from punting.2 (without left) against left.
- Negative slope for leftsq means that increased left-leg strength only increases punting distance up to a point: beyond that, it decreases again.

XXX

Logistic regression (ordinal/nominal response)

Section 3

Logistic regression (ordinal/nominal response)

Logistic regression

- When response variable is measured/counted, regression can work well.
- But what if response is yes/no, lived/died, success/failure?
- Model {probability} of success.
- Probability must be between 0 and 1; need method that ensures this.
- {Logistic regression} does this. In R, is a generalized linear model with binomial "family": glm(ytextasciitilde x,family="binomial")
- Begin with simplest case.

Packages

```
library(MASS)
library(tidyverse)
library(broom)
library(nnet)
```

The rats, part 1

dose status
0 lived
1 died
2 lived

 \bullet Rats given dose of some poison; either live or die: \begin{small}

rats <- read_delim(my_url, " ")

Lecture notes

Basic logistic regression

Data:

rats

```
## # A tibble: 6 x 2
##
      dose status
##
     <dbl> <chr>
         0 lived
## 1
         1 died
## 2
         2 lived
## 3
         3 lived
## 4
## 5
         4 died
         5 died
## 6
```

Make response into a factor first:

```
rats2 <- rats %>% mutate(status = factor(status))
```

Output

summary(status.1)

```
##
## Call:
## glm(formula = status ~ dose, family = "binomial", data = ra
##
## Deviance Residuals:
##
## 0.5835 -1.6254 1.0381 1.3234 -0.7880 -0.5835
##
```

Coefficients:

Lecture notes

Estimate Std. Error z value Pr(>|z|)## (Intercept) 1.6841 1.7979 0.937 0.349 ## dose -0.6736 0.6140 -1.097 0.273 ##

(Dispersion parameter for binomial family taken to be 1) STAD29: Statistics for the Life and Social Sc.

100 / 710

Interpreting the output

- ullet Like (multiple) regression, get tests of significance of individual x's
- Here not significant (only 6 observations).
- "Slope" for dose is negative, meaning that as dose increases, probability of event modelled (survival) decreases.

Output part 2: predicted survival probs

```
p <- predict(status.1, type = "response")
cbind(rats, p)</pre>
```

```
## dose status p
## 1 0 lived 0.8434490
## 2 1 died 0.7331122
## 3 2 lived 0.5834187
## 4 3 lived 0.4165813
## 5 4 died 0.2668878
## 6 5 died 0.1565510
```

def

The rats, more

- More realistic: more rats at each dose (say 10).
- Listing each rat on one line makes a big data file.
- Use format below: dose, number of survivals, number of deaths.

dose	lived	died
0	10	0
1	7	3
2	6	4
3	4	6
4	2	8
5	1	9

- 6 lines of data correspond to 60 actual rats.
- Saved in rat2.txt.

These data

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/rat2.txt"
rat2 <- read_delim(my_url, " ")</pre>
  Parsed with column specification:
## cols(
##
     dose = col double(),
     lived = col double(),
##
     died = col_double()
##
## )
rat2
## # A tibble: 6 x 3
##
      dose lived died
##
     <dbl> <dbl> <dbl>
                10
## 1
          0
                     STAD29: Statistics for the Life and Social Sc.
```

This logistic regression

```
response <- with(rat2, cbind(lived, died))
rat2.1 <- glm(response ~ dose,
  family = "binomial",
  data = rat2
)</pre>
```

- Note construction of two-column response, #survivals in first column, #deaths in second.
- The response variable is an R matrix:

```
class(response)
```

```
## [1] "matrix"
```

Output

```
summary(rat2.1)
```

```
##
## Call:
## glm(formula = response ~ dose, family = "binomial", data =
##
## Deviance Residuals:
## 1 2 3 4 5 6

## 6
```

def

Comments

- Significant effect of dose.
- Effect of larger dose is to decrease survival probability ("slope" negative; also see in decreasing predictions.)

Multiple logistic regression

- With more than one x, works much like multiple regression.
- Example: study of patients with blood poisoning severe enough to warrant surgery. Relate survival to other potential risk factors.
- Variables, 1=present, 0=absent:
- survival (death from sepsis=1), response
- shock
- malnutrition
- alcoholism
- age (as numerical variable)
- bowel infarction
- See what relates to death.

Read in data

```
my url <- "http://www.utsc.utoronto.ca/~butler/d29/sepsis.txt"
sepsis <- read delim(my url, " ")</pre>
## Parsed with column specification:
## cols(
##
     death = col double(),
##
     shock = col double(),
##
     malnut = col double(),
##
     alcohol = col double(),
##
     age = col double(),
##
     bowelinf = col double()
## )
```

                                         2.23 0.0260
## 5 bowelinf
```

Everything significant now.

def

Comments

\$

- Most of the original x's helped predict death. Only malnut seemed not to add anything.
- Removed malnut and tried again.
- Everything remaining is significant (though bowelinf actually became less significant).
- All coefficients are positive, so having any of the risk factors (or being older) increases risk of death.

Predictions from model without "malnut"

A few chosen at random:

def

```
sepsis.pred <- predict(sepsis.2, type = "response")
d <- data.frame(sepsis, sepsis.pred)
myrows <- c(4, 1, 2, 11, 32)
slice(d, myrows)</pre>
```

```

```

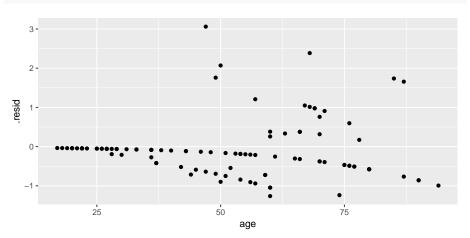

Survival chances pretty good if no risk factors, though decreasing with age.
 Lecture notes
 STAD29: Statistics for the Life and Social Sc
 116/710

Assessing proportionality of odds for age

- An assumption we made is that log-odds of survival depends linearly on age.
- Hard to get your head around, but basic idea is that survival chances go continuously up (or down) with age, instead of (for example) going up and then down.
- In this case, seems reasonable, but should check:

Residuals vs. age

```
ggplot(augment(sepsis.2), aes(x = age, y = .resid)) +
  geom_point()
```

def

Lecture notes

Probability and odds

• For probability p, odds is p/(1-p). Examples:

Prob.	Odds	log-odds	in words
0.5	0.5/0.5 = 1/1 = 1.00	0.00	"even money"
0.1	0.1/0.9 = 1/9 = 0.11	-2.20	"9 to 1"
0.4	0.4/0.6 = 1/1.5 = 0.67	-0.41	"1.5 to 1"
8.0	0.8/0.2 = 4/1 = 4.00	1.39	"4 to 1 on"

- Gamblers use odds: if you win at 9 to 1 odds, get original stake back plus 9 times the stake.
- Probability has to be between 0 and 1
- Odds between 0 and infinity
- Log-odds can be anything: any log-odds corresponds to valid probability.

Odds ratio

- Suppose 90 of 100 men drank wine last week, but only 20 of 100 women.
- Prob of man drinking wine 90/100 = 0.9, woman 20/100 = 0.2.
- Odds of man drinking wine 0.9/0.1 = 9, woman 0.2/0.8 = 0.25.
- Ratio of odds is 9/0.25 = 36.
- Way of quantifying difference between men and women: "odds of drinking wine 36 times larger for males than females".

Sepsis data again

• Recall prediction of probability of death from risk factors:

```
sepsis.2.tidy <- tidy(sepsis.2)
sepsis.2.tidy</pre>
```

```

```

Slopes in column estimate.

sepsis.2.tidy.term expcoeff

(Intercept)

Multiplying the odds

##

1

def

• Can interpret slopes by taking "exp" of them. We ignore intercept.

```
cc <- exp(sepsis.2.tidy$estimate)
data.frame(sepsis.2.tidy$term, expcoeff = round(cc, 2))</pre>
```

0.00

```
## 2 shock 40.50
## 3 alcohol 24.19
## 4 age 1.09
## 5 bowelinf 10.88
```

• These say "how much do you multiply odds of death by for increase of 1 in corresponding risk factor?" Or, what is odds ratio for that factor being 1 (present) vs. 0 (absent)?

STAD29: Statistics for the Life and Social Sc

Odds ratio and relative risk

- Relative risk is ratio of probabilities.
- Above: 90 of 100 men (0.9) drank wine, 20 of 100 women (0.2).
- Relative risk 0.9/0.2=4.5. (odds ratio was 36).
- When probabilities small, relative risk and odds ratio similar.
- Eg. prob of man having disease 0.02, woman 0.01.
- Relative risk 0.02/0.01 = 2. \begin{multicols}{2}
- Odds for men and for women:

```
(od1 \leftarrow 0.02 / 0.98)
```

```
## [1] 0.02040816
```

```
(od2 < -0.01 / 0.99)
```

```
## [1] 0.01010101
```

More than 2 response categories

- With 2 response categories, model the probability of one, and prob of other is one minus that. So doesn't matter which category you model.
- With more than 2 categories, have to think more carefully about the categories: are they
- {ordered}: you can put them in a natural order (like low, medium, high)
- {nominal}: ordering the categories doesn't make sense (like red, green, blue).
- R handles both kinds of response; learn how.

Ordinal response: the miners

- Model probability of being in given category {or lower}.
- Example: coal-miners often suffer disease pneumoconiosis. Likelihood of disease believed to be greater among miners who have worked longer.
- Severity of disease measured on categorical scale: 1 = none, 2 = moderate, 3 = severe.
- Data are frequencies:

Exposu	re 1	None	Moder	ate	Seve	re
5.8	98		0		0	
15.0	5	1	2		1	
21.5	34	4	6		3	
27.5	3	5	5		8	
33.5	3	2	10		9	

Moderate = col_double(),

Severe = col double()

Reading the data

Data in aligned columns with more than one space between, so:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/miners-tab
freqs <- read_table(my_url)

## Parsed with column specification:
## cols(
## Exposure = col_double(),
## None = col_double(),</pre>
```

) def

Creating an ordered factor

- Problem: on plot, Severity categories in wrong order.
- In the data frame, categories in correct order.
- Package forcats (in tidyverse) has functions for creating factors to specifications.
- fct_inorder takes levels in order they appear in data:

```
miners %>%
mutate(sev_ord = fct_inorder(Severity)) -> miners
```

To check:

```
levels(miners$sev_ord)
```

```
## [1] "None" "Moderate" "Severe"
```

New data frame

##
## 1
## 2
        1 88.24324
                         0
```

def Exposure definitely has effect on severity of disease.

Another way

• What (if anything) can we drop from model with exposure?

```
drop1(sev.1, test = "Chisq")
```

```
## Single term deletions
##
## Model:
## sev_ord ~ Exposure
##
           Df
              AIC LRT Pr(>Chi)
## <none> 422.92
## Exposure 1 509.16 88.243 < 2.2e-16 ***
## ---
## Signif. codes:
    0 '***' 0.001 '**' 0.01 '*' 0.05
##
## '.' 0.1 ' ' 1
```

Nothing. Exposure definitely has effect.

Predicted probabilities

Make new data frame out of all the exposure values (from original data frame), and predict from that:

```
sev.new <- tibble(Exposure = freqs$Exposure)
pr <- predict(sev.1, sev.new, type = "p")
miners.pred <- cbind(sev.new, pr)
miners.pred</pre>
```

```

                     STAD29: Statistics for the Life and Social Sc.
```

Comments

- Model appears to match data: as exposure goes up, prob of None goes down, Severe goes up (sharply for high exposure).
- Like original data frame, this one nice to look at but *not tidy*. We want to make graph, so tidy it.
- Also want the severity values in right order.
- Usual gather, plus a bit:

```
miners.pred %>%
gather(Severity, probability, -Exposure) %>%
mutate(sev_ord = fct_inorder(Severity)) -> preds
```

Some of the gathered predictions

preds %>% slice(1:15)

STAD29: Statistics for the Life and Social Sc.

Plotting predicted and observed proportions

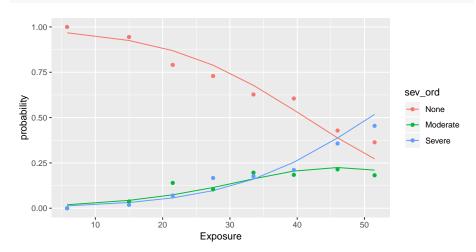

- Plot:
- predicted probabilities, lines (shown) joining points (not shown)
- data, just the points.
- Unfamiliar process: data from two different data frames:

```
g <- ggplot(preds, aes(
    x = Exposure, y = probability,
    colour = sev_ord
)) + geom_line() +
    geom_point(data = miners, aes(y = proportion))</pre>
```

• Idea: final geom_point uses data in miners rather than preds, y-variable for plot is proportion from that data frame, but x-coordinate is Exposure, as it was before, and colour is Severity as before. The final geom_point "inherits" from the first aes as

The plot

g

mlogit.pdf

Unordered responses

- $\bullet \ \ \ With \ unordered \ (nominal) \ responses, \ can \ use \ \{\textit{generalized logit}\}.$
- Example: 735 people, record age and sex (male 0, female 1), which of 3 brands of some product preferred.
- Data in mlogit.csv separated by commas (so read_csv will work):

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/mlogit.csv"
brandpref <- read_csv(my_url)

## Parsed with column specification:
## cols(
## brand = col_double(),
## sex = col_double(),</pre>
```

def

)

##

age = col double()

The data

brandpref

```
##
       brand
                sex
                        age

     ... with 725 more rows
```

A tibble: 735 x 3

Lecture notes

Bashing into shape, and fitting model

• sex and brand not meaningful as numbers, so turn into factors:

```
brandpref <- brandpref %>%
  mutate(sex = factor(sex)) %>%
  mutate(brand = factor(brand))
```

def

We use multinom from package nnet. Works like polr.

```
brands.1 <- multinom(brand ~ age + sex, data = brandpref)</pre>
```

```
## # weights: 12 (6 variable)
## initial value 807.480032
## iter 10 value 702.976983
## final value 702.970704
## converged
```

def

Can we drop anything?

• Unfortunately drop1 seems not to work:

```
drop1(brands.1, test = "Chisq", trace = 0)
```

```
## trying - age
```

Error in if (trace) $\{: argument is not interpretable as log$

 so fall back on fitting model without what you want to test, and comparing using anova.

Do age/sex help predict brand? 1/2

Fit models without each of age and sex:

```
brands.2 <- multinom(brand ~ age, data = brandpref)

## # weights: 9 (4 variable)

## initial value 807.480032

## iter 10 value 706.796323

## iter 10 value 706.796322

## final value 706.796322

## converged

brands.3 <- multinom(brand ~ sex, data = brandpref)</pre>
```

```
## # weights: 9 (4 variable)
## initial value 807.480032
## final value 791.861266
## converged
```

Do age/sex help predict brand? 2/2

```
anova(brands.2, brands.1)
```

```
## Likelihood ratio tests of Multinomial Models
```

```
##
```

1466 1413.593

```
## Response: brand
##
      Model Resid. df Resid. Dev Test Df LR stat.
```

```
##
```

Lecture notes

Likelihood ratio tests of Multinomial Models

1466 1583.723

149 / 710

Response: brand ## Model Resid. df Resid. Dev Test Df LR stat. Pr(

STAD29: Statistics for the Life and Social Sc

2 age + sex 1464 1405.941 1 vs 2 2 177.7811

anova(brands.3, brands.1)

Do age/sex help predict brand? 3/3

- age definitely significant (second anova)
- sex seems significant also (first anova)
- Keep both.

Another way to build model

• Start from model with everything and run step:

```
step(brands.1, trace = 0)
## trying - age
## trying - sex
## Call:
## multinom(formula = brand ~ age + sex, data = brandpref)
##
## Coefficients:
     (Intercept)
##
                      age
                               sex1
## 2 -11.77469 0.3682075 0.5238197
## 3 -22.72141 0.6859087 0.4659488
##
## Residual Deviance: 1405.941
```

Predictions: all possible combinations

Create data frame with various age and sex:

ages \leftarrow c(24, 28, 32, 35, 38)

```
sexes <- factor(0:1)
new <- crossing(age = ages, sex = sexes)</pre>
new
## # A tibble: 10 \times 2
##
        age sex
   <dbl> <fct>
##
##
         24 0
## 2 24 1
##
   3 28 0
     28 1
##
##
     32 0
##
      32 1
         35 0
##
```

Lecture notes

Making predictions

```
p <- predict(brands.1, new, type = "probs")
probs <- cbind(new, p)</pre>
```

The predictions

probs

       38
            1 0.01623089 0.25162197 0.732147148
```

- Young males (sex=0) prefer brand 1, but older males prefer brand 3.
- Females similar, but like brand 1 less and brand 2 more.

Making a plot

Lecture notes

- Plot fitted probability against age, distinguishing brand by colour and gender by plotting symbol.
- Also join points by lines, and distinguish lines by gender.
- I thought about facetting, but this seems to come out clearer.
- First need tidy data frame, by familiar process:

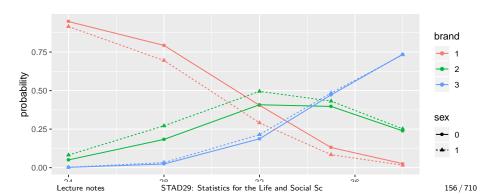

```
probs.long <- probs %>%
  gather(brand, probability, -(age:sex))
sample_n(probs.long, 7) # 7 random rows
```

STAD29: Statistics for the Life and Social Sc

```
## age sex brand probability
## 1 28 0 2 0.18329690
## 2 24 1 3 0.00278882
## 3 35 1 3 0.48427275
## 4 24 1 1 0.91532076
```

The plot

```
ggplot(probs.long, aes(
   x = age, y = probability,
   colour = brand, shape = sex
)) +
   geom_point() + geom_line(aes(linetype = sex))
```

Digesting the plot

- Brand vs. age: younger people (of both genders) prefer brand 1, but older people (of both genders) prefer brand 3. (Explains significant age effect.)
- Brand vs. sex: females (dashed) like brand 1 less than males (solid), like brand 2 more (for all ages). more.
- Not much brand difference between genders (solid and dashed lines of same colours close), but enough to be significant.
- Model didn't include interaction, so modelled effect of gender on brand same for each age, modelled effect of age same for each gender.

Alternative data format

Summarize all people of same brand preference, same sex, same age on one line of data file with frequency on end:

```
1 0 24 1
1 0 26 2
1 0 27 4
1 0 28 4
1 0 29 7
1 0 30 3
```

Whole data set in 65 lines not 735! But how?

Getting alternative data format

```
brandpref %>%
 group_by(age, sex, brand) %>%
 summarize(Freq = n()) %>%
 ungroup() -> b
b %>% slice(1:6)
## # A tibble: 6 x 4
      age sex brand Freq
##
##
    <dbl> <fct> <fct> <int>
    24 0
## 1
## 2
    26 0
    27 0
## 3
    27 1
## 4
    27 1
## 5
       28 0
## 6
```

Fitting models, almost the same

- Just have to remember weights to incorporate frequencies.
- Otherwise multinom assumes you have just 1 obs on each line!
- Again turn (numerical) sex and brand into factors:

```
bf <- b %>%
  mutate(sex = factor(sex)) %>%
  mutate(brand = factor(brand))
b.1 <- multinom(brand ~ age + sex, data = bf, weights = Freq)</pre>
```

```
## # weights: 12 (6 variable)
## initial value 807.480032
## iter 10 value 702.976983
## final value 702.970704
## converged
```

b.2 <- multinom(brand ~ age, data = bf, weights = Freq)</pre>

P-value for sex identical

```
anova(b.2, b.1)

## Likelihood ratio tests of Multinomial Models
##

## Response: brand
## Model Resid. df Resid. Dev Test Df LR stat. If
## 1 age 126 1413.593
## 2 age + sex 124 1405.941 1 vs 2 2 7.651236 0.02

def
```

Same P-value as before, so we haven't changed anything important.

Including data on plot

A tibble: 14×2

 Everyone's age given as whole number, so maybe not too many different ages with sensible amount of data at each:

```
b %>%
group_by(age) %>%
summarize(total = sum(Freq))
```

```
##
        age total
##
      <dbl> <int>
##
         24
##
       26
    3
       27
##
       28
                15
##
##
      29
                19
         30
                23
##
                40
##
      Lecture notes
```

Comments and next

- Not great (especially at low end), but live with it.
- Need proportions of frequencies in each brand for each age-gender combination. Mimic what we did for miners:

```
b %>%
group_by(age, sex) %>%
mutate(proportion = Freq / sum(Freq)) -> brands
```

Checking proportions for age 32

```
brands %>% filter(age == 32)
```

```
## # A tibble: 6 x 5
   # Groups: age, sex [2]
##
       age sex brand Freq proportion
##
     <dbl> <fct> <fct> <int>
                                   <dbl>

## 6
        32 1
                           36
                                   0.167
```

- First three proportions (males) add up to 1.
- Last three proportions (females) add up to 1.
- So looks like proportions of right thing. Lecture notes

Attempting plot

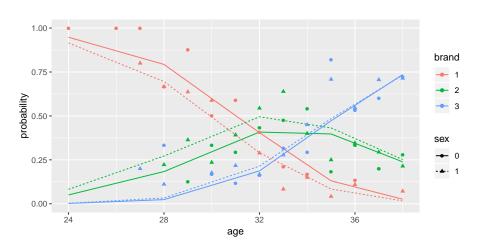

- Take code from previous plot and:
- remove geom_point for fitted values
- add geom_point with correct data= and aes to plot data.

```
g <- ggplot(probs.long, aes(
    x = age, y = probability,
    colour = brand, shape = sex
)) +
    geom_line(aes(linetype = sex)) +
    geom_point(data = brands, aes(y = proportion))</pre>
```

Data seem to correspond more or less to fitted curves:

The plot

g

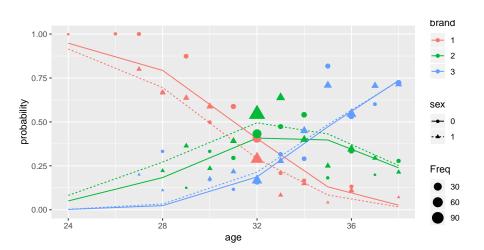

But...

- Some of the plotted points based on a lot of people, and some only a few.
- Idea: make the *size* of plotted point bigger if point based on a lot of people (in Freq).
- Hope that larger points then closer to predictions.
- Code:

```
g <- ggplot(probs.long, aes(
   x = age, y = probability,
   colour = brand, shape = sex
)) +
   geom_line(aes(linetype = sex)) +
   geom_point(
    data = brands,
    aes(y = proportion, size = Freq)</pre>
```

The plot

g

"'r b.4 <- update(b.1, . . + age:sex) "'

Trying interaction between age and gender

```
"' weights: 15 (8 variable) initial value 807.480032 iter 10 value 704.811229 iter 20 value 702.582802 final value 702.582761 converged "'
"'r anova(b.1, b.4) "'
```

- "' Likelihood ratio tests of Multinomial Models Response: brand Model Resid. Dev Test Df 1 age + sex 124 1405.941 2 age + sex + age:sex 122 1405.166 1 vs 2 2 LR stat. Pr(Chi) 1 2 0.7758861 0.678451 "'
 - No evidence that effect of age on brand preference differs for the two genders. «echo=F»= pkgs = names(sessionInfo()\$otherPkgs)
 pkgs=paste('package:', pkgs, sep = "") x=lapply(pkgs, detach, character.only = TRUE, unload = TRUE) @

Section 4

Survival analysis

Survival analysis

- So far, have seen:
- response variable counted or measured (regression)
- response variable categorized (logistic regression)
- and have predicted response from explanatory variables.
 - But what if response is time until event (eg. time of survival after surgery)?
 - Additional complication: event might not have happened at end of study (eg. patient still alive). But knowing that patient has "not died yet" presumably informative. Such data called {censored}.
 - Enter {survival analysis}, in particular the "Cox proportional hazards model".
 - Explanatory variables in this context often called {covariates}.

Example: still dancing?

- 12 women who have just started taking dancing lessons are followed for up to a year, to see whether they are still taking dancing lessons, or have quit. The "event" here is "quit".
- This might depend on:
- a treatment (visit to a dance competition)
- woman's age (at start of study).
- Data: {

Months	Quit	Trea	tment Age
1	1	0	16
2	1	0	24
2	1	0	18
3	0	0	27
4	1 ecture notes	0	25 STAD29: Statistics fo

About the data

- months and quit are kind of combined response:
- Months is number of months a woman was actually observed dancing
- quit is 1 if woman quit, 0 if still dancing at end of study.
- Treatment is 1 if woman went to dance competition, 0 otherwise.
- Fit model and see whether Age or Treatment have effect on survival.
- Want to do predictions for probabilities of still dancing as they depend on whatever is significant, and draw plot.

The code

- Install packages survival and survminer if not done.
- Load survival, survminer, broom and tidyverse packages, read data (column-aligned):

```
library(tidyverse)
library(survival)
library(survminer)
```

```
## Warning: package 'survminer' was built under R version 3.5
```

```
## Warning: package 'ggpubr' was built under R version 3.5.1
## Warning: package 'magrittr' was built under R version 3.5.3
```

```
library(broom)
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/dancing.tx"</pre>
```

dance <- read_table(my_url)</pre>

The data

dance

Examine response and fit model

• Response variable (has to be outside data frame):

```
mth <- with(dance, Surv(Months, Quit))
mth</pre>
```

```
## [1] 1 2 2 3+ 4 5 11 7 8 10 10+ 12
```

• Then fit model, predicting mth from explanatories:

```
dance.1 <- coxph(mth ~ Treatment + Age, data = dance)</pre>
```

def

Output looks a lot like regression

Output looks a lot like regression

summary(dance.1)

```
## Call:
## coxph(formula = mth ~ Treatment + Age, data = dance)
##
## n= 12, number of events= 10
##
                 coef exp(coef) se(coef) z Pr(>|z|)
##
## Treatment -4.44915 0.01169 2.60929 -1.705 0.0882 .
## Age -0.36619 0.69337 0.15381 -2.381 0.0173 *
## Signif. codes:

                                                         177 / 710
```

Conclusions

- Use $\alpha = 0.10$ here since not much data.
- Three tests at bottom like global F-test. Consensus that something predicts survival time (whether or not dancer quit and how long it took).
- Age (definitely), Treatment (marginally) both predict survival time.

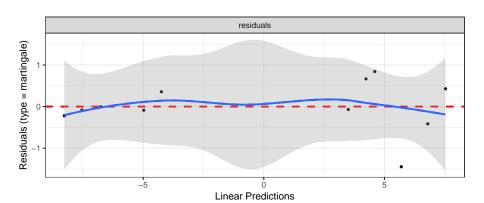

Model checking

- With regression, usually plot residuals against fitted values.
- Not quite same here (nonlinear model), but "martingale residuals" should have no pattern vs. "linear predictor".
- ggcoxdiagnostics from package survminer makes plot, to which we add smooth. If smooth trend more or less straight across, model OK.
- Martingale residuals can go very negative, so won't always look normal.

Martingale residual plot for dance data

```
ggcoxdiagnostics(dance.1) + geom_smooth(se = F)
```

$geom_smooth()$ using method = 'loess' and formula 'y ~ x

Predicted survival probs

The function we use is called survfit, though actually works rather like predict. First create a data frame of values to predict from. We'll do all combos of ages 20 and 40, treatment and not, using crossing to get all the combos:

```
treatments <- c(0, 1)
ages <- c(20, 40)
dance.new <- crossing(Treatment = treatments, Age = ages)
dance.new</pre>
```

```
## # A tibble: 4 x 2
## Treatment Age
## 3 1 20
## 4 1 40
```

The predictions

Lecture notes

One prediction for each time for each combo of age and treatment:

```
s <- survfit(dance.1, newdata = dance.new, data = dance)
summary(s)
```

```
## Call: survfit(formula = dance.1, newdata = dance.new, data
##
```

##	time n.risk	n.event	survival1	survival2	survival3	surviva

##	time	n.rısk	n.event	survivall	survival2	survival3	surviva
##	1	12	1	8.76e-01	1.00e+00	9.98e-01	1.0

##	1	12	1	8.76e-01	1.00e+00	9.98e-01	1.0
##	2	11	2	3 996-01	9 996-01	9 896-01	1 0

11 0.00e+00 0.00e+00 0.00e + 000.00 ## 0.00e+00 0.00e+00 0.00e + 000.00

Conclusions from predicted probs

- Older women more likely to be still dancing than younger women (compare "profiles" for same treatment group).
- Effect of treatment seems to be to increase prob of still dancing (compare "profiles" for same age for treatment group vs. not)
- Would be nice to see this on a graph. This is ggsurvplot from package survminer:

```
g <- ggsurvplot(s, conf.int = F)
```

Plotting survival probabilities

Discussion

A more realistic example: lung cancer

- When you load in an R package, get data sets to illustrate functions in the package.
- One such is lung. Data set measuring survival in patients with advanced lung cancer.
- Along with survival time, number of "performance scores" included, measuring how well patients can perform daily activities.
- Sometimes high good, but sometimes bad!
- Variables below, from the help file data set (?lung).

The variables

Format

inst: Institution code

time: Survival time in days

status: censoring status 1=censored, 2=dead

age: Age in years

sex: Male=1 Female=2

ph.ecog: ECOG performance score (0=good 5=dead)

ph.karno: Karnofsky performance score (bad=0-good=100) rated by physician

pat.karno: Karnofsky performance score as rated by patient

meal.cal: Calories consumed at meals

wt.loss: Weight loss in last six months

Uh oh, missing values

## 2 ph.ecog 0.483 0.000266
anova(lung.3, lung.2)
```

##

A tibble: 2×3

--6:--/

Commentary

- OK (just) to take out those two covariates.
- Both remaining variables strongly significant.
- Effect on survival time:
- Higher value of sex (female) has negative effect on event (death).
- Higher value of ph.ecog has positive effect on death.
- i. e. being female or having lower ph.ecog score has positive effect on survival.
- Picture?

Plotting survival probabilities

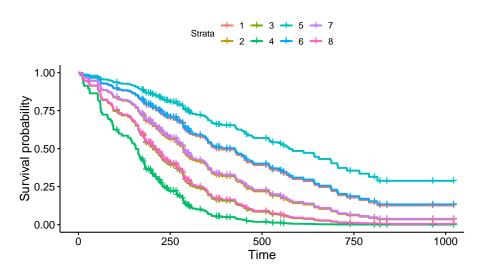

• Create new data frame of values to predict for, then predict:

```
sexes <- c(1, 2)
ph.ecogs <- 0:3
lung.new <- crossing(sex = sexes, ph.ecog = ph.ecogs)
lung.new</pre>
```

```
## # A tibble: 8 \times 2
##
        sex ph.ecog
     <dbl> <int>
##
## 1
## 2
## 3
## 4
      Lecture notes
```

The plot

ggsurvplot(s, conf.int = F)

Discussion of survival curves

- Best survival is teal-blue curve, stratum 5, females with (ph.ecog) score 0.
- Next best: blue, stratum 6, females with score 1, and red, stratum 1, males score 0.
- Worst: green, stratum 4, males score 3.
- For any given ph.ecog score, females have better predicted survival than males.
- For both genders, a lower score associated with better survival.
- sex coeff in model 3 negative, so being higher sex value (female) goes with *less* hazard of dying.
- ph.ecog coeff in model 3 positive, so higher ph.ecog score goes with more hazard of dying
- Two coeffs about same size so heing male rather than female

 Lecture notes STAD29: Statistics for the Life and Social Sc

Martingale residuals for this model

```
ggcoxdiagnostics(lung.3) + geom_smooth(se = F)
```

```
## geom_smooth() using method = 'loess' and formula 'y ~ x
```

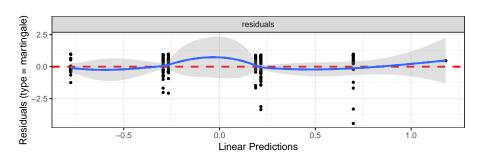

Figure 27: plot of chunk unnamed-chunk-152

No problems here.

When the Cox model fails

 Invent some data where survival is best at middling age, and worse at high and low age:

```
age <- seq(20, 60, 5)
survtime <- c(10, 12, 11, 21, 15, 20, 8, 9, 11)
stat <- c(1, 1, 1, 1, 0, 1, 1, 1, 1)
d <- tibble(age, survtime, stat)
y <- with(d, Surv(survtime, stat))</pre>
```

• Small survival time 15 in middle was actually censored, so would have been longer if observed.

Fit Cox model

```

Section 5

Analysis of variance

Analysis of variance

- Analysis of variance used with:
- counted/measured response
- categorical explanatory variable(s)
- that is, data divided into groups, and see if response significantly different among groups
- or, see whether knowing group membership helps to predict response.
- Typically two stages:
- ullet F-test to detect $\{any\}$ differences among/due to groups
- \bullet if F-test significant, do $\{$ multiple comparisons $\}$ to see which groups significantly different from which.
- Need special multiple comparisons method because just doing (say)
 two-sample t-tests on each pair of groups gives too big a chance of
 Lecture notes
 STAD29: Statistics for the Life and Social Sc
 209 /710

Packages

These:

```
library(tidyverse)
library(broom)
```

Example: Pain threshold and hair colour

- Do people with different hair colour have different abilities to deal with pain?
- Men and women of various ages divided into 4 groups by hair colour: light and dark blond, light and dark brown.
- Each subject given a pain sensitivity test resulting in pain threshold score: higher score is higher pain tolerance.
- 19 subjects altogether.

The data

```
In hairpain.txt:
```

uı uı

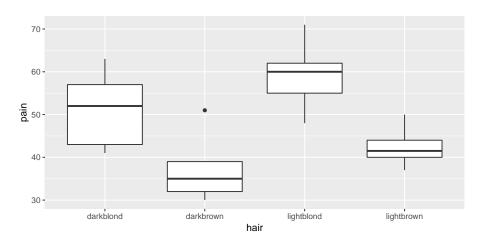

hair pain lightblond 62 lightblond 60 lightblond 71 lightblond 55 lightblond 48 darkblond 63 darkblond 57 darkblond 52 darkblond 41 darkblond 43 lightbrown 42 lightbrown 50 lightbrown 41 lightbrown 37 darkbrown 32 darkbrown 39 darkbrown 51 darkbrown 30 darkbrown 35

Summarizing the groups

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/hairpain.t:
hairpain <- read_delim(my_url, " ")</pre>
## Parsed with column specification:
## cols(
##
     hair = col character(),
     pain = col double()
##
## )
hairpain %>%
  group_by(hair) %>%
  summarize(
    n = n()
    xbar = mean(pain),
    s = sd(pain)
```

Boxplot

ggplot(hairpain, aes(x = hair, y = pain)) + geom_boxplot()

Assumptions

- Data should be:
- normally distributed within each group
- same spread for each group
- darkbrown group has upper outlier (suggests not normal)
- darkblond group has smaller IQR than other groups.
- But, groups small.
- Shrug shoulders and continue for moment.

car::leveneTest(pain ~ hair, data = hairpain)

Testing equality of SDs

• via Levene's test in package car:

```
## Warning in leveneTest.default(y = y, group = group, ...): g
```

```
## Levene's Test for Homogeneity of Variance (center = median)
## Df F value Pr(>F)
## group 3 0.3927 0.76
## 15
```

- No evidence (at all) of difference among group SDs.
- Possibly because groups small.

Analysis of variance

##

```
hairpain.1 <- aov(pain ~ hair, data = hairpain)
summary(hairpain.1)
```

Df Sum Sq Mean Sq F value Pr(>F)

- P-value small: the mean pain tolerances for the four groups are *not* all the same.
- Which groups differ from which, and how?

Multiple comparisons

- Which groups differ from which? Multiple comparisons method. Lots.
- ullet Problem: by comparing all the groups with each other, doing many tests, have large chance to (possibly incorrectly) reject H_0 : groups have equal means.
- 4 groups: 6 comparisons (1 vs 2, 1 vs 3, ..., 3 vs 4). 5 groups: 10 comparisons. Thus 6 (or 10) chances to make mistake.
- Get "familywise error rate" of 0.05 (whatever), no matter how many comparisons you're doing.
- My favourite: Tukey, or "honestly significant differences": how far apart might largest, smallest group means be (if actually no differences). Group means more different: significantly different.

Tukey

TukeyHSD:

```
TukeyHSD(hairpain.1)
##
    Tukey multiple comparisons of means
      95% family-wise confidence level
##
##
  Fit: aov(formula = pain ~ hair, data = hairpain)
##
  $hair
##
                         diff
                                     lwr
                                                upr
                                                        p adj
  darkbrown-darkblond
                        -13.8 -28.696741 1.0967407 0.0740679
                       8.0 -6.896741 22.8967407 0.4355768
## lightblond-darkblond
## lightbrown-darkblond -8.7 -24.500380 7.1003795 0.4147283
## lightblond-darkbrown 21.8 6.903259 36.6967407 0.0037079
## lightbrown-darkbrown 5.1 -10.700380 20.9003795 0.7893211
## lightbrown-lightblond -16.7 -32.500380 -0.8996205 0.0366467
def }
```

The old-fashioned way

- List group means in order
- Draw lines connecting groups that are *not* significantly different:

```
darkbrown lightbrown darkblond lightblond 37.4 42.5 51.2 59.2
```

- lightblond significantly higher than everything except darkblond (at $\alpha=0.05$).
- darkblond in middle ground: not significantly less than lightblond, not significantly greater than darkbrown and lightbrown.
- More data might resolve this.

Lecture notes

• Looks as if blond-haired people do have higher pain tolerance, but not

220 / 710

STAD29: Statistics for the Life and Social Sc

Some other multiple-comparison methods

- Work any time you do k tests at once (not just ANOVA).
- **Bonferroni**: multiply all P-values by k.
- **Holm**: multiply smallest P-value by k, next-smallest by k-1, etc.
- False discovery rate: multiply smallest P-value by k/1, 2nd-smallest by k/2, ..., i-th smallest by k/i.
- Stop after non-rejection.

Example

- P-values 0.005, 0.015, 0.03, 0.06 (4 tests all done at once) Use $\alpha = 0.05$.
- Bonferroni:
- Multiply all P-values by 4 (4 tests).
- Reject only 1st null.
- Holm:
- Times smallest P-value by 4: 0.005 * 4 = 0.020 < 0.05, reject.
- Times next smallest by 3: 0.015 * 3 = 0.045 < 0.05, reject.
- Times next smallest by 2: 0.03*2=0.06>0.05, do not reject. Stop.

...Continued

- With P-values 0.005, 0.015, 0.03, 0.06:
- False discovery rate:
- Times smallest P-value by 4: 0.005 * 4 = 0.02 < 0.05: reject.
- Times second smallest by 4/2: 0.015 * 4/2 = 0.03 < 0.05, reject.
- Times third smallest by 4/3: 0.03 * 4/3 = 0.04 < 0.05, reject.
- Times fourth smallest by 4/4: 0.06*4/4=0.06>0.05, do not reject. Stop.

pairwise.t.test

- "'r attach(hairpain) pairwise.t.test(pain, hair, p.adj = "none")
- "' Pairwise comparisons using t tests with pooled SD data: pain and hair darkblond darkbrown lightblond darkbrown 0.01748 - lightblond 0.14251 0.00075 lightbrown 0.13337 0.36695 0.00817 P value adjustment method: none "'
- "'r pairwise.t.test(pain, hair, p.adj = "holm") "'
- "' Pairwise comparisons using t tests with pooled SD data: pain and hair darkblond darkbrown lightblond darkbrown 0.0699 - lightblond 0.4001 0.0045 lightbrown 0.4001 0.4001 0.0408 P value adjustment method: holm "

- $\hbox{``r pairwise.t.test(pain, hair, p.adj} = \hbox{``fdr")} \hbox{```}$
- "' Pairwise comparisons using t tests with pooled SD data: pain and hair darkblond darkbrown lightblond darkbrown 0.0350 - lightblond 0.1710 0.0045 lightbrown 0.1710 0.3670 0.0245 P value adjustment method: fdr "'
- "'r pairwise.t.test(pain, hair, p.adj = "bon") "'
- "' Pairwise comparisons using t tests with pooled SD data: pain and hair darkblond darkbrown lightblond darkbrown 0.1049 lightblond 0.8550 0.0045 lightbrown 0.8002 1.0000 0.0490 P value adjustment method: bonferroni "'

Comments

- P-values all adjusted upwards from "none".
- Required because 6 tests at once.
- Highest P-values for Bonferroni: most "conservative".
- Prefer Tukey or FDR or Holm.
- Tukey only applies to ANOVA, not to other cases of multiple testing.

Rats and vitamin B

- What is the effect of dietary vitamin B on the kidney?
- A number of rats were randomized to receive either a B-supplemented diet or a regular diet.
- Desired to control for initial size of rats, so classified into size classes lean and obese.
- After 20 weeks, rats' kidneys weighed.
- Variables:
- Response: kidneyweight (grams).
- Explanatory: diet, ratsize.
- Read in data:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/vitaminb.tx
vitaminb <- read_delim(my_url, " ")</pre>
```

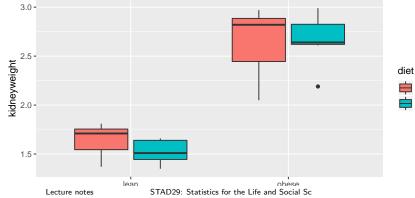

The data

vitaminb

```
## # A tibble: 28 x 3

## # ... with 18 more rows
```

Grouped boxplot

```
ggplot(vitaminb, aes(
   x = ratsize, y = kidneyweight,
   fill = diet
)) + geom_boxplot()
```

What's going on?

Calculate group means:

```
summary <- vitaminb %>%
  group_by(ratsize, diet) %>%
  summarize(mean = mean(kidneyweight))
summary
```

```
## # A tibble: 4 x 3
## # Groups: ratsize [2]
## ratsize diet mean
## <chr> <chr> <chr> <dbl>
## 1 lean regular 1.64
## 2 lean vitaminb 1.53
## 3 obese regular 2.64
## 4 obese vitaminb 2.67
```

Rat size: a large and consistent effect.

vitaminb.1 <- aov(kidneyweight ~ ratsize * diet,</pre>

ANOVA with interaction

```
data = vitaminb
summary(vitaminb.1)
                                       Pr(>F)
##
              Df Sum Sq Mean Sq F value
                         8.068 141.179 1.53e-11 ***
## ratsize
                  8.068
                  0.012 0.012 0.218
## diet
                                        0.645
## ratsize:diet 1 0.036 0.036 0.638
                                        0.432
## Residuals 24 1.372 0.057
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 '
```

(can be removed).

Significance/nonsignificance as we expected. Note no significant interaction

Interaction plot

 Plot mean of response variable against one of the explanatory, using other one as groups. Start from summary:

```
g <- ggplot(summary, aes(
  x = ratsize, y = mean,
  colour = diet, group = diet
)) +
  geom_point() + geom_line()</pre>
```

• For this, have to give both group and colour.

The interaction plot

g

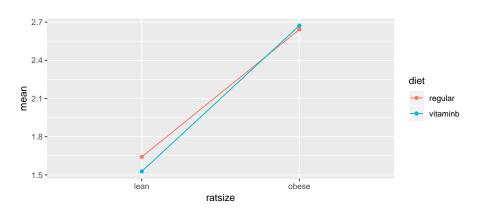

Figure 32: plot of chunk unnamed-chunk-171

Take out interaction

##

```
vitaminb.2 <- update(vitaminb.1, . ~ . - ratsize:diet)
summary(vitaminb.2)</pre>
```

Df Sum Sq Mean Sq F value Pr(>F)

```
## ratsize    1 8.068 8.068 143.256 7.59e-12 ***
## diet    1 0.012 0.012 0.221 0.643
## Residuals    25 1.408 0.056
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 '
```

- No Tukey for diet: not significant.
- No Tukey for ratsize: only two sizes, and already know that obese rats have larger kidneys than lean ones.
- Bottom line: diet has no effect on kidney size once you control for size of rat.

The auto noise data

In 1973, the President of Texaco cited an automobile filter developed by Associated Octel Company as effective in reducing pollution. However, questions had been raised about the effects of filter silencing. He referred to the data included in the report (and below) as evidence that the silencing properties of the Octel filter were at least equal to those of standard silencers.

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/autonoise.t
autonoise <- read_table(my_url)</pre>
```

```
## Parsed with column specification:
## cols(
## noise = col_double(),
## size = col_character(),
## type = col_character(),
## side = col_character()
##

Making boxplot

- Make a boxplot, but have combinations of filter type and engine size.
- Use grouped boxplot again, thus:

```
g <- autonoise %>%
ggplot(aes(x = size, y = noise, fill = type)) +
geom_boxplot()
```

The boxplot

g

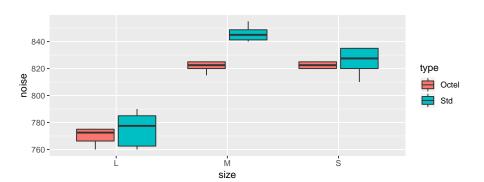

Figure 33: plot of chunk unnamed-chunk-176

Difference in engine noise between Octel and standard is larger for

ANOVA

##

```
autonoise.1 <- aov(noise ~ size * type, data = autonoise)
summary(autonoise.1)</pre>
```

Df Sum Sq Mean Sq F value Pr(>F)

- The interaction is significant, as we suspected from the boxplots.
- The within-group spreads don't look very equal, but only based on 6 obs each.

Tukey: ouch!

11

01

14

12

01

```
autonoise.2 <- TukeyHSD(autonoise.1)</pre>
autonoise.2$`size:type`
```

```
##
                               diff
```

Interaction plot

- This time, don't have summary of mean noise for each size-type combination.
- One way is to compute summaries (means) first, and feed into ggplot as in vitamin B example.
- Or, have ggplot compute them for us, thus:

```
g <- ggplot(autonoise, aes(
    x = size, y = noise,
    colour = type, group = type
)) +
    stat_summary(fun.y = mean, geom = "point") +
    stat_summary(fun.y = mean, geom = "line")</pre>
```

Interaction plot

g

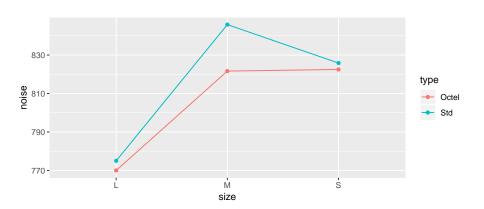

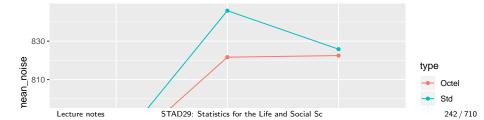

Figure 34: plot of chunk unnamed-chunk-180

If you don't like that...

...then compute the means first, in a pipeline:

```
autonoise %>%
  group_by(size, type) %>%
  summarize(mean_noise = mean(noise)) %>%
  ggplot(aes(
    x = size, y = mean_noise, group = type,
    colour = type
)) + geom_point() + geom_line()
```

Simple effects for auto noise example

- In auto noise example, weren't interested in all comparisons between car size and filter type combinations.
- Wanted to demonstrate (lack of) difference between filter types for each car type.
- These are called **simple effects** of one variable (filter type) conditional on other variable (car type).
- To do this, pull out just the data for small cars, compare noise for the two filter types. Then repeat for medium and large cars. (Three one-way ANOVAs.)

Do it using dplyr tools

• Small cars:

```
autonoise %>%
filter(size == "S") %>%
aov(noise ~ type, data = .) %>%
summary()
```

```
## Df Sum Sq Mean Sq F value Pr(>F)
## type 1 33.3 33.33 0.548 0.476
## Residuals 10 608.3 60.83
```

- No filter difference for small cars.
- For Medium, change S to M and repeat.

Simple effect of filter type for medium cars

```
autonoise %>%
 filter(size == "M") %>%
 aov(noise ~ type, data = .) %>%
 summary()
##
              Df Sum Sq Mean Sq F value Pr(>F)
## type 1 1752.1 1752.1 68.93 8.49e-06 ***
## Residuals 10 254.2 25.4
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

autonoise %>% filter(size == "M") %>% Lecture notes STAD29: Statistics for the Life and Social Sc.

• There is an effect of filter type for medium cars. Look at means to

investigate: {

Medium and large cars

- Octel filters produce less noise for medium cars.
- Large cars:

```
autonoise %>%
  filter(size == "L") %>%
  aov(noise ~ type, data = .) %>%
  summary()
```

```
## Df Sum Sq Mean Sq F value Pr(>F)
## type 1 75 75 0.682 0.428
## Residuals 10 1100 110
```

- No significant difference again.
- Or use glance from broom:

```
autonoise %>%
  filter(size == "L") %>%
```

All at once, using split/apply/combine

```
The "split" part:
```

A tibble: 3 x 2

```
autonoise %>%
  group_by(size) %>%
  nest()
```

```
## size data
## <chr> tibble [12 × 3]>
## 2 L <tibble [12 × 3]>
## 3 S <tibble [12 × 3]>
```

Now have *three* rows, with the data frame for each size encoded as *one element* of this data frame.

Apply

 Write function to do aov on a data frame with columns noise and type, returning P-value:

```
aov_pval <- function(x) {
  noise.1 <- aov(noise ~ type, data = x)
  gg <- glance(noise.1)
  gg$p.value
}</pre>
Test it:
```

```
autonoise %>%
  filter(size == "L") %>%
  aov_pval()
```

```
## [1] 0.428221
```

Check.

Combine

 Apply this function to each of the nested data frames (one per engine size):

```
autonoise %>%
  group_by(size) %>%
  nest() %>%
  mutate(p_val = map_dbl(data, ~ aov_pval(.)))
```

map_dbl because aov_pval returns a decimal number (a dbl).
 Investigate what happens if you use map instead.

Tidy up

 The data column was stepping-stone to getting answer. Don't need it any more:

```
simple_effects <- autonoise %>%
  group_by(size) %>%
  nest() %>%
  mutate(p_val = map_dbl(data, ~ aov_pval(.))) %>%
  select(-data)
simple_effects
```

```
## size p_val
## <chr> <dbl>
## 1 M 0.00000849
## 2 L 0.428
## 3 S 0.476
```

A tibble: 3 x 2

Simultaneous tests

- When testing simple effects, doing several tests at once. (In this case,3.)
- Have to adjust P-values for this. Eg. Holm:

```
simple_effects %>%
  arrange(p_val) %>%
  mutate(multiplier = 4 - row_number()) %>%
  mutate(p_val_adj = p_val * multiplier)
```

^{*} No change in rejection decisions.

Confidence intervals

- Perhaps better way of assessing simple effects: look at *confidence intervals* rather than tests.
- Gives us sense of accuracy of estimation, and thus whether non-significance might be lack of power: "absence of evidence is not evidence of absence".
- Works here because two filter types, using t.test for each engine type.
- Want to show that the Octel filter is equivalent to or better than the standard filter, in terms of engine noise.

Equivalence and noninferiority

- Known as "equivalence testing" in medical world. A good read: link. Basic idea: decide on size of difference δ that would be considered "equivalent", and if CI entirely inside $\pm \delta$, have evidence in favour of equivalence.
- We really want to show that the Octel filters are "no worse" than the standard one: that is, equivalent *or better* than standard filters.
- Such a "noninferiority test" done by checking that upper limit of CI, new minus old, is *less* than δ . (This requires careful thinking about (i) which way around the difference is and (ii) whether a higher or lower value is better.)

CI for small cars

Same idea as for simple effect test:

```
autonoise %>%
  filter(size == "S") %>%
  t.test(noise ~ type, data = .) %>%
  .[["conf.int"]]
```

```
## [1] -14.517462 7.850795
## attr(,"conf.level")
## [1] 0.95
```

CI for medium cars

```
autonoise %>%
  filter(size == "M") %>%
  t.test(noise ~ type, data = .) %>%
  .[["conf.int"]]
```

```
## [1] -30.75784 -17.57549
## attr(,"conf.level")
## [1] 0.95
```

CI for large cars

```
autonoise %>%
  filter(size == "L") %>%
  t.test(noise ~ type, data = .) %>%
  .[["conf.int"]]
## [1] -19.270673 9.270673
```

attr(,"conf.level")

[1] 0.95

Or, all at once: split/apply/combine

```
ci_func <- function(x) {
  tt <- t.test(noise ~ type, data = x)
  tt$conf.int
}
cis <- autonoise %>%
  group_by(size) %>%
  nest() %>%
  mutate(ci = map(data, ~ ci_func(.))) %>%
  unnest(ci)
```

```
"' A tibble: 6 x 2 size ci <chr>
```

* Function to get CI of difference in

"'r cis "'

<dbl> 1 M -30.8 2 M -17.6 3 L -19.3 4 L 9.27 5 S -14.5 6 S 7.85 "'

* Calculate CI for each thing in 'data' (ie. each 'size'). 'map': CI is two

* Group by 'size', nest (mini-df per size)

numbers long

noise means for types of filter on input * 'unnect' 'ci' column to see two
Lecture notes STAD29: Statistics for the Life and Social Sc

Cls and noninferiority test

- Suppose we decide that a 20 dB difference would be considered equivalent. (I have no idea whether that is reasonable.)
- Intervals:

```
cis %>%
  mutate(hilo = rep(c("lower", "upper"), 3)) %>%
  spread(hilo, ci)

## # A tibble: 3 x 3
```

```
## size lower upper
## <chr> <dbl> <dbl>
## 1 L -19.3 9.27
## 2 M -30.8 -17.6
## 3 S -14.5 7.85
```

\begin{tabular}{lrr}

Contrasts in ANOVA

- Sometimes, don't want to compare all groups, only some of them.
- Might be able to specify these comparisons ahead of time; other comparisons of no interest.
- Wasteful to do ANOVA and Tukey.

Example: chainsaw kickback

- From link.
- Forest manager concerned about safety of chainsaws issued to field crew. 4 models of chainsaws, measure "kickback" (degrees of deflection) for 5 of each:

So far, standard 1-way ANOVA: what differences are there among models?

chainsaw kickback (2)

- But: models A and D are designed to be used at home, while models B and C are industrial models.
- Suggests these comparisons of interest:
- home vs. industrial
- the two home models A vs. D
- the two industrial models B vs. C.
- Don't need to compare all the pairs of models.

What is a contrast?

- Contrast is a linear combination of group means.
- Notation: μ_A for (population) mean of group A, and so on.
- In example, compare two home models: $H_0: \mu_A \mu_D = 0$.
- Compare two industrial models: $H_0: \mu_B \mu_C = 0$.
- Compare average of two home models vs. average of two industrial models: $H_0:\frac{1}{2}(\mu_A+\mu_D)-\frac{1}{2}(\mu_B+\mu_C)=0$ or $H_0:0.5\mu_A-0.5\mu_B-0.5\mu_C+0.5\mu_D=0$.
- Note that coefficients of contrasts add to 0, and right-hand side is 0.

Contrasts in R

• Comparing two home models A and D ($\mu_A - \mu_D = 0$):

$$c.home <- c(1, 0, 0, -1)$$

• Comparing two industrial models B and C ($\mu_B - \mu_C = 0$):

c.industrial
$$\leftarrow c(0, 1, -1, 0)$$

• Comparing home average vs. industrial average $(0.5\mu_A - 0.5\mu_B - 0.5\mu_C + 0.5\mu_D = 0)$:

c.home.ind
$$\leftarrow c(0.5, -0.5, -0.5, 0.5)$$

Orthogonal contrasts

• What happens if we multiply the contrast coefficients one by one?

```
c.home * c.industrial
```

```
## [1] 0 0 0 0
```

c.home * c.home.ind

```
## [1] 0.5 0.0 0.0 -0.5
```

c.industrial * c.home.ind

```
## [1] 0.0 -0.5 0.5 0.0
```

 in each case, the results add up to zero. Such contrasts are called orthogonal.

Orthogonal contrasts (2)

Compare these:

```
c1 <- c(1, -1, 0)
c1
```

```
## [1] 1 -1 0 c2 \leftarrow c(0, 1, -1)
```

c2

c1 * c2

Does not add up to zero, so c1 and c2 are not orthogonal.

- Orthogonal contrasts are much easier to deal with.
- Can use non arthuranal contracts but much more trouble (and bound Lecture notes STAD29: Statistics for the Life and Social Sc 265/710

Starting the analysis

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/chainsaw.tx

Section 6

Analysis of covariance

Analysis of covariance

- ANOVA: explanatory variables categorical (divide data into groups)
- traditionally, analysis of covariance has categorical x's plus one numerical x ("covariate") to be adjusted for.
- 1m handles this too.
- Simple example: two treatments (drugs) (a and b), with before and after scores.
- Does knowing before score and/or treatment help to predict after score?
- Is after score different by treatment/before score?

Data

Treatment, before, after:

III III

a 5 20 a 10 23 a 12 30 a 9 25 a 23 34 a 21 40 a 14 27 a 18 38 a 6 24 a 13 31 b 7 19 b 12 26 b 27 33 b 24 35 b 18 30 b 22 31 b 26 34 b 21 28 b 14 23 b 9 22

## 3 drugb
                                    -4.00 9.21e- 4
```

- before ordinary numerical variable; drug categorical.
- 1m uses first category druga as baseline.
- Intercept is prediction of after score for before score 0 and *drug A*.
- before slope is predicted change in after score when before score increases by 1 (usual slope)
- Slope for drugb is change in predicted after score for being on drug B
 Lecture notes
 STAD29: Statistics for the Life and Social Sc
 290 /710

Summary

- ANCOVA model: fits different regression line for each group, predicting response from covariate.
- ANCOVA model with interaction between factor and covariate allows different slopes for each line.
- Sometimes those lines can cross over!
- If interaction not significant, take out. Lines then parallel.
- With parallel lines, groups have consistent effect regardless of value of covariate.

Section 7

Multivariate ANOVA

Multivariate analysis of variance

- Standard ANOVA has just one response variable.
- What if you have more than one response?
- Try an ANOVA on each response separately.
- But might miss some kinds of interesting dependence between the responses that distinguish the groups.

## fertilizer 1 3.125 3.125 1.471 0.271
## Residuals 6 12.750 2.125
def }
```

Neither response depends significantly on fertilizer. But...

Plotting both responses at once

Have two response variables (not more), so can plot the response variables against *each other*, labelling points by which fertilizer group they're from.

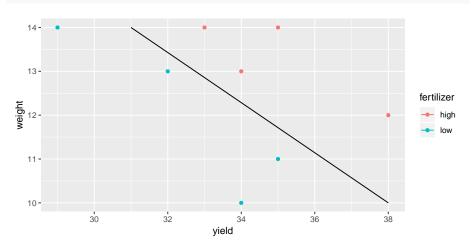

```
g <- ggplot(hilo, aes(
    x = yield, y = weight,
    colour = fertilizer
)) + geom_point()</pre>
```

Want line through points (31, 14) and (38, 10) (why? Later):

Lecture notes

The plot

g

def

MANOVA

g

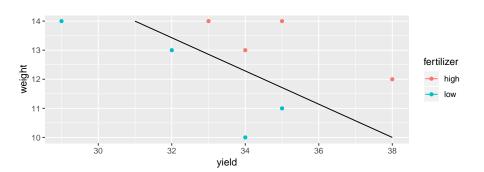

Figure 37: plot of chunk unnamed-chunk-233

- * High-fertilizer plants have both yield and weight high.
- * True even though no sig difference in vield or weight individually.

 Lecture notes STAD29: Statistics for the Life and Social Sc

MANOVA finds multivariate differences

• Is difference found by diagonal line significant? MANOVA finds out.

```
response <- with(hilo, cbind(yield, weight))
hilo.1 <- manova(response ~ fertilizer, data = hilo)
summary(hilo.1)</pre>
```

```
## Df Pillai approx F num Df den Df Pr(>F)

## fertilizer 1 0.80154 10.097 2 5 0.01755 *

## Residuals 6

## ---

## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 '

def
```

 Yes! Difference between groups is diagonally, not just up/down (weight) or left-right (yield). The yield-weight combination matters.

Strategy

- Create new response variable by gluing together columns of responses, using cbind.
- Use manova with new response, looks like 1m otherwise.
- With more than 2 responses, cannot draw graph. What then?
- If MANOVA test significant, cannot use Tukey. What then?
- Use {discriminant analysis} (of which more later).

Another way to do MANOVA

Install (once) and load package car:

library(car)

def

Another way...

```
hilo.2.lm <- lm(response ~ fertilizer, data = hilo)
hilo.2 <- Manova(hilo.2.lm)
hilo.2
##</pre>
```

```
## Type II MANOVA Tests: Pillai test statistic
## Df test stat approx F num Df den Df Pr(>F)
## fertilizer 1 0.80154 10.097 2 5 0.01755 *
## ---
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 '
```

- Same result as small-m manova
- Manova will also do repeated measures, coming up later.

Another example: peanuts

- Three different varieties of peanuts (mysteriously, 5, 6 and 8) planted in two different locations.
- Three response variables: y, smk and w.

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/peanuts.tx
(peanuts.orig <- read_delim(my_url, " "))</pre>
```

Section 8

Repeated measures by profile analysis

Repeated measures by profile analysis

- More than one response {measurement} for each subject. Might be
- measurements of the same thing at different times
- measurements of different but related things
- Generalization of matched pairs ("matched triples", etc.).
- Variation: each subject does several different treatments at different times (called {crossover design}).
- Expect measurements on same subject to be correlated, so assumptions of independence will fail.
- Called {repeated measures}. Different approaches, but {profile analysis} uses Manova (set up right way).
- Another approach uses mixed models (random effects).

STAD29: Statistics for the Life and Social Sc

Example: histamine in dogs

- 8 dogs take part in experiment.
- Dogs randomized to one of 2 different drugs.
- Response: log of blood concentration of histamine 0, 1, 3 and 5 minutes after taking drug. (Repeated measures.)
- Data in dogs.txt, column-aligned.

Read in data

```
my url <- "http://www.utsc.utoronto.ca/~butler/d29/dogs.txt"
dogs <- read table(my url)</pre>
## Parsed with column specification:
## cols(
##
     dog = col_character(),
##
     drug = col character(),
     x = col character(),
##
##
     lh0 = col double(),
     lh1 = col double(),
##
##
     lh3 = col double(),
```

) lh5 = col double()

```

Getting the times

Not quite right: for the times, we want just the numbers, not the letters 1h every time. Want new variable containing just number in time: parse_number.

```
dogs %>%
  gather(timex, lh, lh0:lh5) %>%
  mutate(time = parse_number(timex)) %>%
  print(n = 10)
```

```
A tibble: 32 \times 6
##

##
      Lecture notes
                      STAD29: Statistics for the Life and Social Sc
```

What I did differently

- I realized that gather was going to produce something like 1h1, which
 I needed to do something further with, so this time I gave it a
 temporary name timex.
- This enabled me to use the name time for the actual numeric time.
- This works now, so next save into a new data frame dogs.long.

Saving the chained results

```
dogs.long <- dogs %>%
  gather(timex, lh, lh0:lh5) %>%
  mutate(time = parse_number(timex))
```

This says:

- Take data frame dogs, and then:
- Combine the columns 1h0 through 1h5 into one column called 1h, with the column that each 1h value originally came from labelled by timex, and then:
- Pull out numeric values in timex, saving in time and then:
- save the result in a data frame dogs.long.

reshape

- Converts between wide and long format.
- Need to tell R what our repeated-measures responses are.
- Convenient variable naming: all responses are 1h followed by a number representing time.
- Like this:
- «»= detach(dogs) d2=reshape(dogs,varying=3:6,sep="", direction="long")
- @ %def

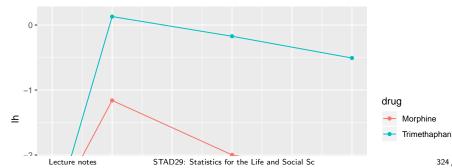

Long data frame, top 12 lines

$$= head(d2,n=12) @ def$$

id labels dog, time labels time. Perfect for interaction plot.

Interaction plot

```
ggplot(dogs.long, aes(
   x = time, y = lh,
   colour = drug, group = drug
)) +
   stat_summary(fun.y = mean, geom = "point") +
   stat_summary(fun.y = mean, geom = "line")
```

Comments

- Plot mean 1h value at each time, joining points on same drug by lines.
- drugs same at time 0
- after that, Trimethaphan higher than Morphine.
- Effect of drug not consistent over time: significant interaction.

Take out time zero

- Lines on interaction plot would then be parallel, and so interaction should no longer be significant.
- Go back to original "wide" dogs data frame.

```
response <- with(dogs, cbind(lh1, lh3, lh5)) # excluding time
dogs.lm <- lm(response ~ drug, data = dogs)
times <- colnames(response)
times.df <- data.frame(times)
dogs.manova <- Manova(dogs.lm,
   idata = times.df,
   idesign = ~times
)</pre>
```

def

Correct: interaction no longer significant.

drug:times 1 0.43553 1.9289

- Significant effect of time.
- 3 Significant effect of time

Lecture notes

5 0.008105 **

5 0.239390

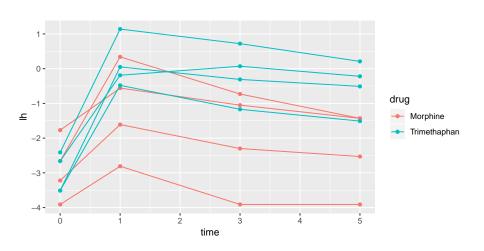

Is the non-significant drug effect reasonable?

- Plot actual data: 1h against days, labelling observations by drug: "spaghetti plot".
- Uses long data frame (confusing, yes I know):
- Plot (time,lh) points coloured by drug
- and connecting measurements for each dog by lines.
- This time, we want group=dog (want the measurements for each dog joined by lines), but colour=drug:

```
g <- ggplot(dogs.long, aes(
    x = time, y = lh,
    colour = drug, group = dog
)) +
    geom_point() + geom_line()</pre>
```

The spaghetti plot

g

Comments

- For each dog over time, there is a strong increase and gradual decrease in log-histamine. This explains the significant time effect.
- The pattern is more or less the same for each dog, regardless of drug. This explains the non-significant interaction.
- Most of the trimethaphan dogs (blue) have higher log-histamine throughout (time 1 and after), and some of the morphine dogs have lower.
- But two of the morphine dogs have log-histamine profiles like the trimethaphan dogs. This ambiguity is probably why the drug effect is not quite significant.

The exercise data

- 30 people took part in an exercise study.
- Each subject was randomly assigned to one of two diets ("low fat" or "non-low fat") and to one of three exercise programs ("at rest", "walking", "running").
- There are $2 \times 3 = 6$ experimental treatments, and thus each one is replicated 30/6 = 5 times.
- Nothing unusual so far.
- However, each subject had their pulse rate measured at three different times (1, 15 and 30 minutes after starting their exercise), so have repeated measures.

Reading the data

Separated by tabs:

```
exercise.long <- read_tsv(my_url)

## Parsed with column specification:
## cols(
## id = col_double(),
## diet = col_character(),
## exertype = col_character(),
## pulse = col_double(),
## time = col_character()
## time = col_character()</pre>
```

my_url <- "http://www.utsc.utoronto.ca/~butler/d29/exercise.tx

The data

```
exercise.long %>% print(n = 8)
```

```
## # A tibble: 90 \times 5
##
       id diet exertype pulse time
    <dbl> <chr> <dbl> <chr> <dbl> <chr>
##
        1 nonlowfat atrest
## 1
                              85 min01
## 2
        1 nonlowfat atrest 85 min15
        1 nonlowfat atrest 88 min30
## 3
## 4
        2 nonlowfat atrest 90 min01
## 5
        2 nonlowfat atrest 92 min15
        2 nonlowfat atrest 93 min30
## 6
## 7
        3 nonlowfat atrest 97 min01
        3 nonlowfat atrest 97 min15
## 8
## # ... with 82 more rows
```

This is "long format", which is usually what we want.

Making wide format

 Spread needs three things: a data frame, a column that is going to be split, and the column to make the values out of:

```
exercise.wide <- spread(exercise.long, time, pulse)
exercise.wide %>% print(n = 6)
```

```
## # A tibble: 30 \times 6
##
        id diet
                   exertype min01 min15 min30
##
     <dbl> <chr> <chr>
                               <dbl> <dbl> <dbl> <dbl>
                                  85
## 1
         1 nonlowfat atrest
                                        85
                                               88
## 2
         2 nonlowfat atrest
                                  90
                                        92
                                               93
## 3
         3 nonlowfat atrest
                                97
                                        97
                                               94
## 4
         4 nonlowfat atrest
                                  80
                                        82
                                               83
## 5
         5 nonlowfat atrest
                                  91
                                        92
                                               91
## 6
         6 lowfat atrest
                                  83
                                         83
                                               84
## # ... with 24 more rows
```

Setting up the repeated-measures analysis

Make a response variable consisting of min01, min15, min30:

```
response <- with(
  exercise.wide,
  cbind(min01, min15, min30)
)</pre>
```

Predict that from diet and exertype and interaction using lm:

```
exercise.1 <- lm(response ~ diet * exertype,
  data = exercise.wide
)</pre>
```

• Run this through Manova:

```
times <- colnames(response)
times.df <- data.frame(times)
exercise.2 <- Manova(exercise.1,</pre>
```

Results

```
"'r exercise 2 "'
```

- "' Type II Repeated Measures MANOVA Tests: Pillai test statistic Df test stat approx F num Df den Df Pr(>F) (Intercept) 1 0.99767 10296.7 1 24 < 2.2e-16 *** diet 1 0.37701 14.5 1 24 0.0008483 *** exertype 2 0.79972 47.9 2 24 4.166e-09 *** diet:exertype 2 0.28120 4.7 2 24 0.0190230 * times 1 0.78182 41.2 2 23 2.491e-08 *** diet:times 1 0.25153 3.9 2 23 0.0357258 * exertype:times 2 0.83557 8.6 4 48 2.538e-05 *** diet:exertype:times 2 0.51750 4.2 4 48 0.0054586 ** Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1 "'
 - Three-way interaction significant, so cannot remove anything.
 - Pulse rate depends on diet and exercise type combination, and that is different for each time.

Making some graphs

- Three-way interactions are difficult to understand. To make an attempt, look at some graphs.
- Plot time trace of pulse rates for each individual, joined by lines, and make separate plots for each diet-exertype combo.
- ggplot again. Using long data frame:

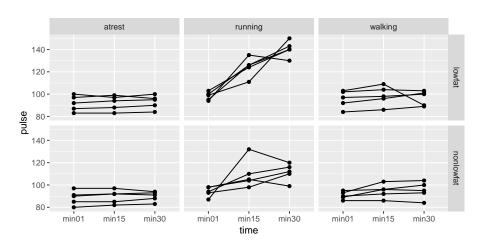

```
g <- ggplot(exercise.long, aes(
   x = time, y = pulse,
   group = id
)) + geom_point() + geom_line() +
   facet_grid(diet ~ exertype)</pre>
```

• facet_grid(diet~exertype): do a separate plot for each combination of diet and exercise type, with diets going down the page and exercise types going across. (Graphs are usually landscape, so have the factor exertype with more levels going across.)

Lecture notes STAD29: Statistics for the Life and Social Sc 337/710

The graph(s)

g

Comments on graphs

- For subjects who were at rest, no change in pulse rate over time, for both diet groups.
- For walking subjects, not much change in pulse rates over time. Maybe a small increase on average between 1 and 15 minutes.
- For both running groups, an overall increase in pulse rate over time, but the increase is stronger for the lowfat group.
- No consistent effect of diet over all exercise groups.
- No consistent effect of exercise type over both diet groups.
- No consistent effect of time over all diet-exercise type combos.

"Simple effects" of diet for the subjects who ran

- Looks as if there is only any substantial time effect for the runners. For them, does diet have an effect?
- Pull out only the runners from the wide data:

```
runners.wide <- exercise.wide %>%
filter(exertype == "running")
```

 Create response variable and do MANOVA. Some of this looks like before, but I have different data now:

```
response <- with(runners.wide, cbind(min01, min15, min30))
runners.1 <- lm(response ~ diet, data = runners.wide)
times <- colnames(response)
times.df <- data.frame(times)
runners.2 <- Manova(runners.1,
   idata = times.df,
   idesign = ~times</pre>
```

Results

```
runners.2
##

##
## Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

- The diet by time interaction is still significant (at $\alpha=0.05$): the effect of time on pulse rates is different for the two diets.
- At $\alpha=0.01$, the interaction is not significant, and then we have only two (very) significant main effects of diet and time.

How is the effect of diet different over time?

• Table of means. Only I need long data for this, so make it (in a pipe):

```
summ <- runners.wide %>%
  gather(time, pulse, min01:min30) %>%
  group_by(time, diet) %>%
  summarize(
   mean = mean(pulse),
   sd = sd(pulse)
)
```

• Result of summarize is data frame, so can save it (and do more with it if needed).

Understanding diet-time interaction

• The summary:

```
summ
```

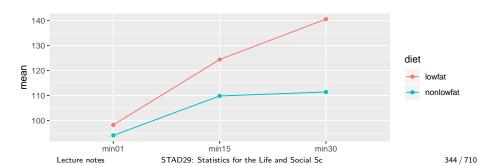

```
## # A tibble: 6 x 4
## # Groups: time [3]
## time diet mean sd
## <chr> <chr> <chr> <dbl> <dbl> <## 1 min01 lowfat 98.2 3.70
## 2 min01 nonlowfat 94 4.53
## 3 min15 lowfat 124. 8.62
## 4 min15 nonlowfat 110. 13.1
## 5 min30 lowfat 141. 7.20
## 6 min30 nonlowfat 111. 7.92</pre>
```

- Pulse rates at any given time higher for lowfat (diet effect),
- Pulse rates increase over time of exercise (time effect),

Interaction plot

 We went to trouble of finding means by group, so making interaction plot is now mainly easy:

```
ggplot(summ, aes(
  x = time, y = mean, colour = diet,
  group = diet
)) + geom_point() + geom_line()
```

Section 9

Discriminant analysis

Discriminant analysis

- ANOVA and MANOVA: predict a (counted/measured) response from group membership.
- Discriminant analysis: predict group membership based on counted/measured variables.
- Covers same ground as logistic regression (and its variations), but emphasis on classifying observed data into correct groups.
- Does so by searching for linear combination of original variables that best separates data into groups (canonical variables).
- Assumption here that groups are known (for data we have). If trying to "best separate" data into unknown groups, see {cluster analysis}.
- Examples: revisit seed yield and weight data, peanut data, professions/activities data; remote-sensing data.

Packages

##

```
library(MASS)
library(tidyverse)
```

```
## ggplot2 3.1.1 purrr 0.3.2
## tibble 2.1.1 dplyr 0.8.0.1
## tidyr 0.8.3.9000 stringr 1.4.0
## readr 1.3.1 forcats 0.3.0
## Warning: package 'ggplot2' was built under R version 3.5.3
```

Attaching packages tidyverse 1.2.1

Warning: package 'readr' was built under R version 3.5.2
Warning: package 'purrr' was built under R version 3.5.3

Warning: package 'tibble' was built under R version 3.5.3

Warning: package 'tidyr' was built under R version 3.5.3

About select

- Both dplyr (in tidyverse) and MASS have a function called select, and they do different things.
- How do you know which select is going to get called?
- With library, the one loaded *last* is visible, and others are not.
- Thus we can access the select in dplyr but not the one in MASS. If we wanted that one, we'd have to say MASS::select.
- This is why I loaded MASS before tidyverse. If I had done it the other way around, the tidyverse select, which I want to use, would have been the invisible one.

Example 1: seed yields and weights

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/manova1.txf
hilo <- read_delim(my_url, " ")
g <- ggplot(hilo, aes(
    x = yield, y = weight,
    colour = fertilizer
)) + geom_point(size = 4)</pre>
```

"'r g "'
![plot of chunk berzani](figure/berzani-1.pdf)

Recall data from MANOVA: needed a multivariate analysis to find difference in seed yield and weight based on whether they were high or low fertilizer.

Basic discriminant analysis

```
hilo.1 <- lda(fertilizer ~ yield + weight, data = hilo)
```

- Uses 1da from package MASS.
- "Predicting" group membership from measured variables.

Output

Lecture notes

hilo.1 ## Call: ## lda(fertilizer ~ yield + weight, data = hilo) ## ## Prior probabilities of groups: ## high low ## 0.5 0.5 ## ## Group means: yield weight ## ## high 35.0 13.25 ## low 32.5 12.00 ## ## Coefficients of linear discriminants: ## LD1 ## π iald =0 7666761

STAD29: Statistics for the Life and Social Sc.

Things to take from output

- Group means: high-fertilizer plants have (slightly) higher mean yield and weight than low-fertilizer plants.
- "Coefficients of linear discriminants": LD1, LD2,...are scores constructed from observed variables that best separate the groups.
- \bullet For any plant, get LD1 score by taking -0.76 times yield plus -1.25 times weight, add up, standardize.
- Understand by pretending all variables standardized (mean 0, + above mean, below mean). If yield and weight high (above average), contribute a + to LD1 score, so LD1 negative. If yield and weight low (think -), LD1 score positive.
- High-fertilizer plants have higher yield and weight, thus negative LD1 score. Low-fertilizer plants have low yield and weight, thus positive LD1 score.
- One I D1 score for each observation. Plot with actual grouns
 Lecture notes. STAD29: Statistics for the Life and Social Sc.

How many linear discriminants?

- Number of variables
- Number of groups minus 1
- Smaller of these
- Seed yield and weight: 2 variables, 2 groups, $\min(2, 2-1) = 1$.

Getting LD scores

```
Feed output from LDA into predict:
```

```
hilo.pred <- predict(hilo.1)
```

Component x contains LD score(s), here in descending order:

```
d <- cbind(hilo, hilo.pred\x) %>% arrange(desc(LD1))
```

```
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict_prefer()`
## * conflict_prefer("arrange", "plyr")
## * conflict_prefer("arrange", "dplyr")
d
```

Plotting LD1 scores

With one LD score, plot against (true) groups, eg. boxplot:

```
ggplot(d, aes(x = fertilizer, y = LD1)) + geom_boxplot()
```

```
## Error in FUN(X[[i]], ...): object 'fertilizer' not found
```

Potentially misleading

• These are like regression slopes:

```
hilo.1$scaling
```

```
## LD1
## yield -0.7666761
## weight -1.2513563
```

- Reflect change in LD1 score for 1-unit change in variables.
- But one-unit change in variables might not be comparable:

summary(hilo)

```

```

Understanding the predicted groups

- Each predicted fertilizer level is exactly same as observed one (perfect prediction).
- Table shows no errors: all values on top-left to bottom-right diagonal.

Posterior probabilities

show how clear-cut the classification decisions were:

```
pp <- round(hilo.pred$posterior, 4)
d <- cbind(hilo, hilo.pred$x, pp)
d</pre>
```

```

\$ Only obs. 7 has any doubt: yield low for a high-fertilizer, but high

Contour plot of LD1

First, get some new yield and weight values for prediction. Then predict LD1 for them:

Then: plot original data, and overlay contours showing value of LD1 for each yield and weight (over):

Contour plot

```
\begin{minipage}[t]{0.7}
«santini,fig.height=5» = plot(yield,weight,col=fno,pch=fno)
z=matrix(hilo.pred$x,length(yy), length(ww),byrow=F)
contour(yy,ww,z,add=T) @
\end{minipage}
*
'LD1'
<
0:

                                                                                                                                  194.
                                                                                                                                                                           164. 57.8
##
                                      Lecture notes
                                                                                                                                  STAD29: Statistics for the Life and Social Sc.
```

Discriminant analysis

```
peanuts.1 <- lda(combo ~ y + smk + w, data = peanuts.combo)
peanuts.1$scaling</pre>
```

```
## LD1 LD2 LD3
## y -0.4027356 -0.02967881 0.18839237
## smk -0.1727459 0.06794271 -0.09386294
## w 0.5792456 0.16300221 0.07341123
```

peanuts.1\$svd

```
## [1] 6.141323 2.428396 1.075589
```

- Now 3 LDs (3 variables, 6 groups, min(3, 6-1) = 3).
- First: relationship of LDs to original variables. Look for coeffs far from zero: here,
- high LD1 mainly high w or low y.

Group means by variable

peanuts.1\$means

```
## y smk w
## 5_1 194.80 160.40 52.55
## 5_2 185.05 130.30 49.95
## 6_1 199.45 161.40 47.80
## 6_2 200.15 163.95 57.25
## 8_1 190.25 164.80 58.20
## 8_2 200.75 170.30 66.10
$
```

- 5_2 clearly smallest on y, smk, near smallest on w
- 8_2 clearly biggest on smk, w, also largest on y
- 8_1 large on w, small on y.
- scaling links LDs with original variables, means links original Lecture notes
 STAD29: Statistics for the Life and Social Sc

The predictions and misclassification

```
peanuts.pred <- predict(peanuts.1)
table(
  obs = peanuts.combo$combo,
  pred = peanuts.pred$class
)</pre>
```

```

Discriminant scores, again

I.D1

- How are discriminant scores related to original variables?
- Construct data frame with original data and discriminant scores side by side:

LD3

```
peanuts.1$scaling
```

##

LD2

Discriminant scores for data

mm

```
##
    combo y smk w LD1 LD2 LD3
## 1 5_1 195.3 153.1 51.4 -1.42 -1.01 0.26
## 2 5 1 194.3 167.7 53.7 -2.20 0.38 -1.13
## 3 5 2 189.7 139.5 55.5 5.56 -1.10 0.79
## 4 5 2 180.4 121.1 44.4 6.06 -3.89 -0.05
## 5 6 1 203.0 156.8 49.8 -6.08 -1.25 1.25
## 6 6_1 195.9 166.0 45.8 -7.13 -1.07 -1.24
      6 2 202.7 166.1 60.4 -1.43 1.12 1.10
## 7
## 8 6_2 197.6 161.8 54.1 -2.28 -0.05 0.08
## 9 8_1 193.5 164.5 57.8 1.05 0.86 -0.67
## 10  8_1 187.0 165.1 58.6  4.02  1.22 -1.90
## 11 8 2 201.5 166.8 65.0 1.60 1.95 1.15
## 12  8_2 200.0 173.8 67.2 2.27 2.83 0.37
```

Obs. 5 and 6 have most negative LD1: large y, small w.

Predict typical LD1 scores

First and third quartiles for three response variables (reading down):

```
quartiles <- peanuts %>%
  select(y:w) %>%
  map df(quantile, c(0.25, 0.75))
quartiles
## # A tibble: 2 x 3
##
             \mathtt{smk}
##
   <dbl> <dbl> <dbl>
## 1 193. 156. 51
## 2 200. 166. 59.0
new <- with(quartiles, crossing(y, smk, w))</pre>
```

The combinations

new

```
# A tibble: 8 x 3
##
            smk
##
    <dbl> <dbl> <dbl>
    193. 156.
## 1
                51
## 2
    193. 156. 59.0
## 3 193. 166. 51
## 4
    193. 166. 59.0
    200.
           156.
                 51
## 5
     200.
           156.
                 59.0
## 6
    200. 166.
                 51
## 7
## 8
     200.
           166.
                 59.0
```

pp <- predict(peanuts.1, new)</pre>

Predicted typical LD1 scores

```
cbind(new, pp$x) %>% arrange(LD1)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict prefer()`
## * conflict_prefer("arrange", "plyr")
## * conflict_prefer("arrange", "dplyr")

    Very negative LD1 score with large y and small w
```

- smk doesn't contribute much to LD1
- Very positive LD1 score with small y and large w.
- Same as we saw from Coefficients of Linear Discriminants.

Plot LD1 vs. LD2, labelling by combo

```
g <- ggplot(mm, aes(
    x = LD1, y = LD2, colour = combo,
    label = combo
)) + geom_point() +
    geom_text_repel() + guides(colour = F)
g</pre>
```

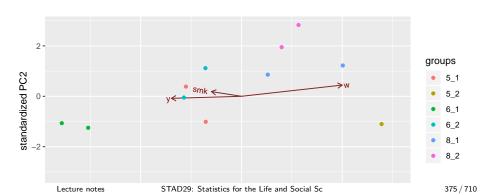

"Bi-plot" from ggbiplot

```
«echo=F,message=F»= library(plyr) library(tidyverse) library(ggbiplot) @

«eval=F»= library(ggbiplot) @

ggbiplot(peanuts.1,
    groups = factor(peanuts.combo$combo)
)
```

Installing ggbiplot

- ggbiplot not on CRAN, so usual install.packages will not work.
- Install package devtools first (once):

```
install.packages("devtools")
```

Then install ggbiplot (once):

```
library(devtools)
install_github("vqv/ggbiplot")
```

Cross-validation

- So far, have predicted group membership from same data used to form the groups — dishonest!
- Better: *cross-validation*: form groups from all observations *except one*, then predict group membership for that left-out observation.
- No longer cheating!
- Illustrate with peanuts data again.

Misclassifications

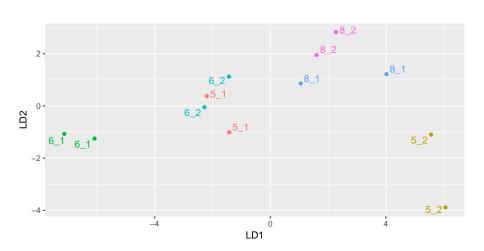

• Fitting and prediction all in one go:

```
peanuts.cv <- lda(combo ~ y + smk + w,
  data = peanuts.combo, CV = T
)
table(
  obs = peanuts.combo$combo,
  pred = peanuts.cv$class
)</pre>
```

```
##
         pred
## obs
           5_1 5_2 6_1 6_2 8_1 8_2
     5_1
                  0
##
     5 2 0
##
     6_1 0
##
                  0
     6_2 1
                  0
##
      8 1
##
      Lecture notes
                       STAD29: Statistics for the Life and Social Sc
```

Repeat of LD plot

g

pp <- round(peanuts.cv\$posterior, 3)</pre>

Posterior probabilities

```
data.frame(
  obs = peanuts.combo$combo,
  pred = peanuts.cv$class, pp
##
      obs pred X5 1 X5 2 X6 1 X6 2 X8 1 X8 2

## 9 8 1 8 2 0.000 0.00 0.000 0.000 0.000 1.000
     Lecture notes
                   STAD29: Statistics for the Life and Social Sc
```

Why more misclassification?

- When predicting group membership for one observation, only uses the *other one* in that group.
- So if two in a pair are far apart, or if two groups overlap, great potential for misclassification.
- Groups 5_1 and 6_2 overlap.
- 5_2 closest to 8_1s looks more like an 8_1 than a 5_2 (other one far away).
- 8_1s relatively far apart and close to other things, so one appears to be a 5_2 and the other an 8_2.

Example 3: professions and leisure activities

- 15 individuals from three different professions (politicians, administrators and belly dancers) each participate in four different leisure activities: reading, dancing, TV watching and skiing. After each activity they rate it on a 0–10 scale.
- Some of the data:

```
bellydancer 7 10 6 5
bellydancer 8 9 5 7
bellydancer 5 10 5 8
politician 5 5 5 6
politician 4 5 6 5
admin 4 2 2 5
admin 7 1 2 4
admin 6 3 3 3
```

How can we hest use the scores on the activities to predict a person's

STAD29: Statistics for the Life and Social Sc

382/710

Discriminant analysis

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/profile.tx
active <- read_delim(my_url, " ")</pre>
active.1 <- lda(job ~ reading + dance + tv + ski, data = active
active.1$svd
```

```
active.1$scaling
```

[1] 9.856638 3.434555

```
##
                 LD1
                           LD2
## reading -0.01297465 0.4748081
## dance -0.95212396 0.4614976
## tv -0.47417264 -1.2446327
## ski
          0.04153684 0.2033122
```

Two discriminants, first fair bit more important than second.

STAD29: Statistics for the Life and Social Sc

LD1 depends (negatively) most on dance, a bit on tv.

5

Misclassification

admin

##

##

##

```
active.pred <- predict(active.1)
table(obs = active$job, pred = active.pred$class)

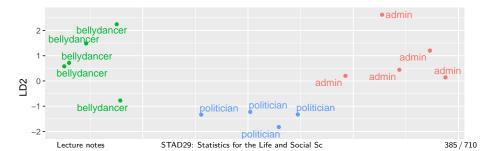

## pred
## obs admin bellydancer politician</pre>
```

Everyone correctly classified.

bellydancer politician

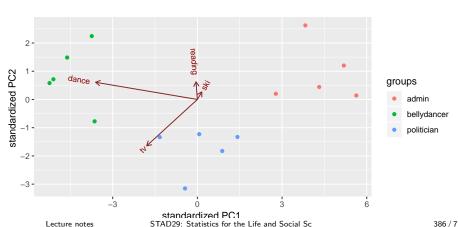

Plotting LDs

```
mm <- data.frame(job = active$job, active.pred$x, person = 1::
g <- ggplot(mm, aes(
    x = LD1, y = LD2,
    colour = job, label = job
)) + geom_point() +
    geom_text_repel() + guides(colour = F)
g</pre>
```

Biplot

ggbiplot(active.1, groups = active\$job)

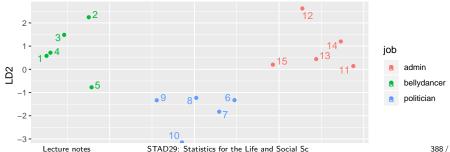

Comments on plot

- Groups well separated: bellydancers top left, administrators top right, politicians lower middle.
- Bellydancers most negative on LD1: like dancing most.
- Administrators most positive on LD1: like dancing least.
- Politicians most negative on LD2: like TV-watching most.

Plotting individual persons

Make label be identifier of person. Now need legend:

```
ggplot(mm, aes(
   x = LD1, y = LD2,
   colour = job, label = person
)) + geom_point() +
   geom_text_repel()
```

Posterior probabilities

Lecture notes

```
pp <- round(active.pred$posterior, 3)</pre>
data.frame(obs = active$job, pred = active.pred$class, pp)
##
              obs
                          pred admin bellydancer politician

STAD29: Statistics for the Life and Social Sc

389 / 710

Cross-validating the jobs-activities data

Recall: no need for predict. Just pull out class and make a table:

```
active.cv <- lda(job ~ reading + dance + tv + ski,
   data = active, CV = T
)
table(obs = active$job, pred = active.cv$class)</pre>
```

```
## pred
## obs admin bellydancer politician
## admin 5 0 0
## bellydancer 0 4 1
## politician 0 0 5
```

This time one of the bellydancers was classified as a politician.

and look at the posterior probabilities

picking out the ones where things are not certain:

```
pp <- round(active.cv$posterior, 3)</pre>
data.frame(obs = active$job, pred = active.cv$class, pp) %>%
  mutate(max = pmax(admin, bellydancer, politician)) %>%
  filter(max < 0.9995)
```

```
## [conflicted] `mutate` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::mutate
## * dplyr::mutate
## Or declare a preference with `conflict prefer()`
## * conflict_prefer("mutate", "plyr")
## * conflict_prefer("mutate", "dplyr")
$
```

Bellydancer was "definitely" a politician! Lecture notes

Why did things get misclassified?

![plot of chunk nesta](figure/nesta-1.pdf)

- * Go back to plot of discriminant scores:
- one bellydancer much closer to the politicians,
- * one administrator a bit closer to the politicians.

Example 4: remote-sensing data

- View 38 crops from air, measure 4 variables x1-x4.
- Go back and record what each crop was.
- Can we use the 4 variables to distinguish crops?

Reading in

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/remote-sens
crops <- read_table(my_url)</pre>
## Parsed with column specification:
## cols(
     crop = col_character(),
##
##
     x1 = col double(),
     x2 = col double(),
##
     x3 = col double(),
##
##
     x4 = col double(),
```

cr = col character()

##

)

Starting off: number of LDs

```
crops.lda <- lda(crop ~ x1 + x2 + x3 + x4, data = crops) crops.lda$svd
```

```
## [1] 2.2858251 1.1866352 0.6394041 0.2303634
```

- 4 LDs (four variables, six groups).
- 1st one important, maybe 2nd as well.

Connecting original variables and LDs

crops.lda\$means

```
## x1 x2 x3 x4
## Clover 46.36364 32.63636 34.18182 36.63636
## Corn 15.28571 22.71429 27.42857 33.14286
## Cotton 34.50000 32.66667 35.00000 39.16667
## Soybeans 21.00000 27.00000 23.50000 29.66667
## Sugarbeets 31.00000 32.16667 20.00000 40.50000
```

```
round(crops.lda$scaling, 3)
```

```
## LD1 LD2 LD3 LD4

## x1 -0.061 0.009 -0.030 -0.015

## x2 -0.025 0.043 0.046 0.055

## x3 0.016 -0.079 0.020 0.009

## x4 0.000 -0.014 0.054 -0.026
```

links grouns to original variables to I Ds Lecture notes STAD29: Statistics for the Life and Social Sc

LD1 and texttt{LD2}

round(crops.lda\$scaling, 3)

```
## LD1 LD2 LD3 LD4

## x1 -0.061 0.009 -0.030 -0.015

## x2 -0.025 0.043 0.046 0.055

## x3 0.016 -0.079 0.020 0.009

## x4 0.000 -0.014 0.054 -0.026
```

- LD1 mostly x1 (minus), so clover low on LD1, corn high.
- LD2 x3 (minus), x2 (plus), so sugarbeets should be high on LD2.

Predictions

Thus:

```
crops.pred <- predict(crops.lda)
table(obs = crops$crop, pred = crops.pred$class)</pre>
```

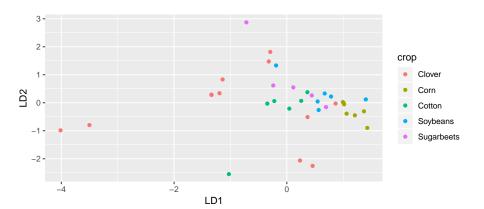

##		pred				
##	obs	Clover	${\tt Corn}$	${\tt Cotton}$	Soybeans	Sugarbeets
##	Clover	6	0	3	0	2
##	Corn	0	6	0	1	0
##	Cotton	3	0	1	2	0
##	Soybeans	0	1	1	3	1
##	Sugarbeets	: 1	1	0	2	2

- Not very good, eg. only 6 of 11 Clover classified correctly.
- Set up for plot:

```
mm <- data.frame(crop = crops$crop, crops.pred$x)</pre>
```

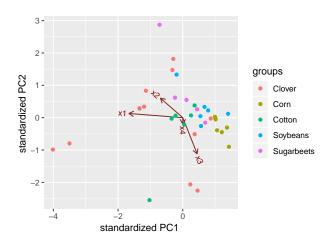

Plotting the LDs

```
ggplot(mm, aes(x = LD1, y = LD2, colour = crop)) +
geom_point()
```

Biplot

ggbiplot(crops.lda, groups = crops\$crop)

Try removing Clover

• the dplyr way:

```
crops %>% filter(crop != "Clover") -> crops2
crops2.lda <- lda(crop ~ x1 + x2 + x3 + x4, data = crops2)</pre>
```

- LDs for crops2 will be different from before.
- Concentrate on plot and posterior probs.

```
crops2.pred <- predict(crops2.lda)
mm <- data.frame(crop = crops2$crop, crops2.pred$x)</pre>
```

lda output

Different from before:

```
crops2.lda$means
```

```
## x1 x2 x3 x4

## Corn 15.28571 22.71429 27.42857 33.14286

## Cotton 34.50000 32.66667 35.00000 39.16667

## Soybeans 21.00000 27.00000 23.50000 29.66667

## Sugarbeets 31.00000 32.16667 20.00000 40.50000

crops2.lda$svd
```

crops2.lda\$scaling

Lecture notes

```
## LD1 LD2 LD3
## x1 0.14077479 0.007780184 -0.0312610362
```

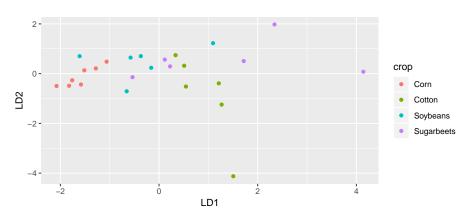

STAD29: Statistics for the Life and Social Sc.

[1] 3.3639389 1.6054750 0.4180292

Plot

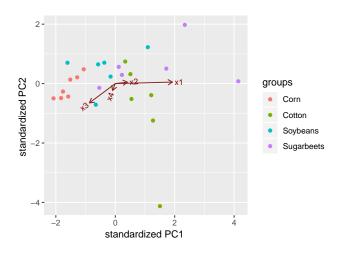

A bit more clustered:

```
ggplot(mm, aes(x = LD1, y = LD2, colour = crop)) +
  geom_point()
```

Biplot

ggbiplot(crops2.lda, groups = crops2\$crop)

Quality of classification

```
table(obs = crops2$crop, pred = crops2.pred$class)
```

```
## obs Corn Cotton Soybeans Sugarbeets
## Corn 6 0 1 0
## Cotton 0 4 2 0
## Soybeans 2 0 3 1
## Sugarbeets 0 0 3 3
```

Better.

Posterior probs, the wrong ones

```
def {
post <- round(crops2.pred$posterior, 3)
data.frame(obs = crops2$crop, pred = crops2.pred$class, post) %>%
  filter(obs != pred)
```

```
##

##
    Sugarbeets
                Soybeans 0.106 0.144
    Sugarbeets
                                       0.518
                                                 0.232
  9 Sugarbeets
                Soybeans 0.088
                               0.207
                                       0.489
                                                 0.216
```

 These were the misclassified ones, but the posterior probability of being correct was not usually too low.

MANOVA

##

Began discriminant analysis as a followup to MANOVA. Do our variables significantly separate the crops (excluding Clover)?

```
response <- with(crops2, cbind(x1, x2, x3, x4))
crops2.manova <- manova(response ~ crop, data = crops2)</pre>
summary(crops2.manova)
```

Df Pillai approx F num Df den Df Pr(>F)

```
3 0.9113 2.1815 12
## crop
                                         60 0.02416 *
## Residuals 21
## ---
## Signif. codes:
## 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

Yes, at least one of the crops differs (in means) from the others. So it is worth doing this analysis.

We did this the wrong way around, though! STAD29: Statistics for the Life and Social Sc.

The right way around

- First, do a MANOVA to see whether any of the groups differ significantly on any of the variables.
- If the MANOVA is significant, do a discriminant analysis in the hopes of understanding how the groups are different.
- For remote-sensing data (without Clover):
- LD1 a fair bit more important than LD2 (definitely ignore LD3).
- LD1 depends mostly on x1, on which Cotton was high and Corn was low.
- Discriminant analysis in MANOVA plays the same kind of role that Tukey does in ANOVA.

Section 10

Cluster analysis

Cluster Analysis

- One side-effect of discriminant analysis: could draw picture of data (if 1st 2s LDs told most of story) and see which individuals "close" to each other.
- Discriminant analysis requires knowledge of groups.
- Without knowledge of groups, use {cluster analysis}: see which individuals close, which groups suggested by data.
- Idea: see how individuals group into "clusters" of nearby individuals.
- Base on "dissimilarities" between individuals.
- Or base on standard deviations and correlations between variables (assesses dissimilarity behind scenes).

9	neuf	nueve	nove	dziewiec	kilenc	yhdeksan
10	dix	diez	dieci	dziesiec	tiz	kymmenen

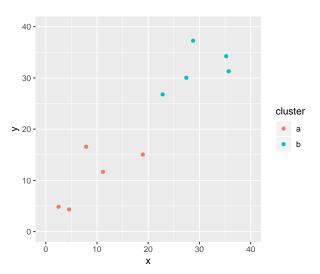

Dissimilarities and languages example

- Can define dissimilarities how you like (whatever makes sense in application).
- Sometimes defining "similarity" makes more sense; can turn this into dissimilarity by subtracting from some maximum.
- Example: numbers 1–10 in various European languages. Define similarity between two languages by counting how often the same number has a name starting with the same letter (and dissimilarity by how often number has names starting with different letter).
- Crude (doesn't even look at most of the words), but see how effective.

Two kinds of cluster analysis

- Looking at process of forming clusters (of similar languages):
 hierarchical cluster analysis (hclust).
- Start with each individual in cluster by itself.
- Join "closest" clusters one by one until all individuals in one cluster.
- How to define closeness of two clusters? Not obvious, investigate in a moment.
- Know how many clusters: which division into that many clusters is "best" for individuals? **K-means clustering** (kmeans).

Two made-up clusters

Single-linkage distance

```
Find the red point and the blue point that are closest together:
## Error in loadNamespace(j <- i[[1L]], c(lib.loc, .libPaths()</pre>
## Error in apply(distances, 1, min): object 'distances' not
## Error in apply(distances, 2, min): object 'distances' not :
## Error in `[.data.frame`(a, wm1, ): object 'wm1' not found
## Error in fortify(data): object 'closest' not found
Single-linkage distance between 2 clusters is distance between their closest
points.
```

Complete-linkage distance is distance between farthest points.

Complete linkage

```
Find the red and blue points that are farthest apart:

## Error in apply(distances, 1, max): object 'distances' not :

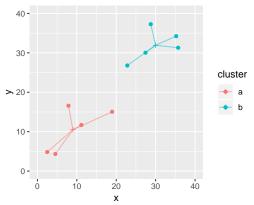

## Error in apply(distances, 2, max): object 'distances' not :

## Error in `[.data.frame`(a, wm1, ): object 'wm1' not found

## Error in fortify(data): object 'closest' not found
```

Ward's method

Work out mean of each cluster and join point to its mean:

Work out sum of squared distances of points from means.

Ward's method part 2

Now imagine combining the two clusters and working out overall mean. Join each point to this mean:

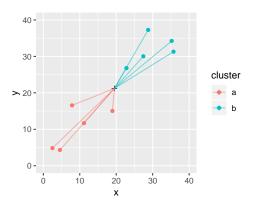

Figure 53: plot of chunk unnamed-chunk-325

Ward's method part 3

- will be bigger than (i) (points closer to own cluster mean than combined mean).
- Ward's distance is (ii) minus (i).
- Think of as "cost" of combining clusters:
- if clusters close together, (ii) only a little larger than

• if clusters far apart, (ii) a lot larger than (i) (as in example).

Hierarchical clustering revisited

- Single linkage, complete linkage, Ward are ways of measuring closeness of clusters.
- Use them, starting with each observation in own cluster, to repeatedly combine two closest clusters until all points in one cluster.
- They will give different answers (clustering stories).
- Single linkage tends to make "stringy" clusters because clusters can be very different apart from two closest points.
- Complete linkage insists on whole clusters being similar.
- Ward tends to form many small clusters first.

Dissimilarity data in R

A tibble: 11 x 12

##

es Lecture notes

Dissimilarities for language data were how many number names had different* first letter:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/languages.t
number.d <- read_table(my_url)
number.d</pre>
```

```

Cluster analysis and dendrogram

```
d.hc <- hclust(d, method = "single")
plot(d.hc)</pre>
```

Cluster Dendrogram

Comments

- Tree shows how languages combined into clusters.
- First (bottom), Spanish, French, Italian joined into one cluster, Norwegian and Danish into another.
- Later, English joined to Norse languages, Polish to Romance group.
- Then German, Dutch make a Germanic group.
- Finally, Hungarian and Finnish joined to each other and everything else.

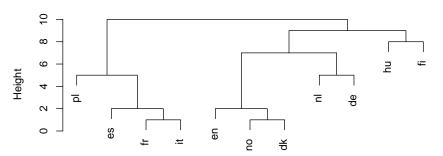

Clustering process

```
def
"'r d.hclabels"
"' [1] "en" "no" "dk" "nl" [5] "de"
"fr" "es" "it" [9] "pl" "hu" "fi" "'
                                    * Lines of 'merge' show what was com-
"'r d.hcmerge"
                                     bined
"' [,1] [,2] [1,] -2 -3 [2,] -6 -8 [3,]
-7 2 [4,] -1 1 [5,] -9 3 [6,] -5 4 [7,] * First, languages 2 and 3 ('no' and
-4 6 [8,] 5 7 [9,] -10 8 [10,] -11 9 "' 'dk')
                                    * Then languages 6 and 8 ('fr' and 'it')
                                    * Then #7 combined with cluster
                                     formed at step 2 ('es' joined to 'fr'
                                     and 'it').
                                    * Then 'en' joined to 'no' and 'dk' ...
                                    * Finally 'fi' joined to all others.
```

Complete linkage

```
d.hc <- hclust(d, method = "complete")
plot(d.hc)</pre>
```

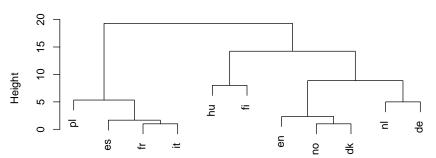

Cluster Dendrogram

Ward

```
d.hc <- hclust(d, method = "ward.D")
plot(d.hc)</pre>
```

Cluster Dendrogram

Chopping the tree

cutree(d.hc, 3)

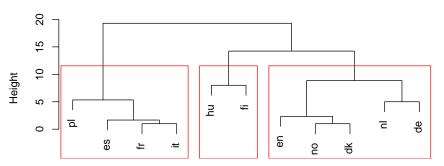

• Three clusters (from Ward) looks good:

```
## en no dk nl de fr es it
## 1 1 1 1 1 2 2 2
## pl hu fi
## 2 3 3
```

Drawing those clusters on the tree

```
plot(d.hc)
rect.hclust(d.hc, 3)
```

Cluster Dendrogram

Comparing single-linkage and Ward

- In Ward, Dutch and German get joined earlier (before joining to Germanic cluster).
- Also Hungarian and Finnish get combined earlier.

Making those dissimilarities

....
```

Calculating dissimilarity

- Suppose we wanted dissimilarity between English and Norwegian. It's the number of first letters that are different.
- First get the lines for English:

```
english <- lang.long %>% filter(language == "en")
english
```

```
A tibble: 10 \times 4
##
      number language name first
##
       <int> <chr>
                        <chr> <chr>
##
    1
            1 en
                        one
##
            2 en
                        two
            3 en
                        three t
##
##
            4 en
                        four
            5 en
                        five
##
##
              en
                        six
```

And then the lines for Norwegian

```
norwegian <- lang.long %>% filter(language == "no")
norwegian
```

```
A tibble: 10 \times 4
##

Another example

Birth, death and infant mortality rates for 97 countries (variables not dissimilarities):

```
24.7 5.7
         30.8 Albania
                            12.5 11.9 14.4 Bulgaria
13.4 11.7 11.3 Czechoslovakia
                            12 12.4 7.6 Former_E._Germany
11.6 13.4 14.8 Hungary
                            14.3 10.2
                                        16 Poland
13.6 10.7
         26.9 Romania
                                      20.2 Yugoslavia
                              14
17.7 10 23 USSR
                            15.2 9.5
                                      13.1 Byelorussia_SSR
13.4 11.6 13 Ukrainian SSR
                            20.7 8.4
                                      25.7 Argentina
46.6 18 111 Bolivia
                            28.6 7.9
                                        63 Brazil
23.4 5.8 17.1 Chile
                                        40 Columbia
                            27.4 6.1
           63 Ecuador
32.9 7.4
                            28.3 7.3
                                        56 Guyana
. . .
}
```

- Want to find groups of similar countries (and how many groups, which countries in each group).
- Tree would be unwieldy with 97 countries.

```

Standardizing

- Infant mortality rate numbers bigger than others, consequence of measurement scale (arbitrary).
- Standardize (numerical) columns of data frame to have mean 0, SD 1, done by scale.

```
vital.s <- vital %>% mutate_if(is.numeric, scale)
```

Three clusters

Pretend we know 3 clusters is good. Take off the 4th column (of countries) and run kmeans on the resulting data frame, asking for 3 clusters:

```
vital.km3 <- vital.s %>% select(-4) %>% kmeans(3)
names(vital.km3)
```

```
## [1] "cluster" "centers" "totss"
## [4] "withinss" "tot.withinss" "betweenss"
## [7] "size" "iter" "ifault"
```

A lot of output, so look at these individually.

What's in the output?

Cluster sizes:

vital.km3\$size

```
## [1] 29 44 24
def
```

Cluster centres:

```
vital.km3$centers
```

```
birth
                 death
                            infant
##
    0.4737967 -0.4878149 0.2466440
  2 -0.9593341 -0.4322350 -0.8904328
## 3 1.1862748 1.3818738 1.3344318
```

def

 Cluster 2 has lower than average rates on everything; cluster 3 has Lecture notes

Cluster sums of squares and membership

```
## [1] 14.96356 25.13922 26.78049
def
Cluster 1 compact relative to others (countries in cluster 1 more similar).
vital.km3$cluster
   \lceil 1 \rceil 2 2 2 2 2 3 2 1 1 2 3 2 2 2 2 2 2 2 2 3 1 2 2 1 1

  [85] 3 3 3 3 1 3 3 3 3 3 1 3 3
```

·

The cluster membership for each of the 97 countries.

def

vital.km3\suithinss

Store countries and clusters to which they belong

```
vital.3 <- tibble(
  country = vital.s$country,
  cluster = vital.km3$cluster
)</pre>
```

Next, which countries in which cluster?

Write function to extract them:

```
get_countries <- function(i, d) {
  d %>% filter(cluster == i) %>% pull(country)
}
```

Cluster membership: cluster 2

get_countries(2, vital.3)

```

                        "Saudi_Arabia" "Indonesia"
## [22] "Lebanon"
## [25] "Malaysia"
                        "Philippines" "Vietnam"
                        "Tunisia"
   [28] "Kenva"
```

Problem!

- kmeans uses randomization. So result of one run might be different from another run.
- Example: just run again on 3 clusters, table of results:

```
vital.km3a <- vital.s %>% select(-4) %>% kmeans(3)
table(
  first = vital.km3$cluster,
  second = vital.km3a$cluster
)
```

STAD29: Statistics for the Life and Social Sc.

```
## second

## first 1 2 3

## 1 1 0 28

## 2 0 40 4

## 3 24 0 0
```

Clusters are similar but not same.

How many clusters?

- Three was just a guess.
- Idea: try a whole bunch of #clusters (say 2-20), obtain measure of goodness of fit for each, make plot.
- Appropriate measure is tot.withinss.
- Use loop to run kmeans for each #clusters, keep track of tot.withinss.

Function to get tot.withinss

...for an input number of clusters, taking only numeric columns of input data frame:

```
ss <- function(i, d) {
  km <- d %>%
    select_if(is.numeric) %>%
    kmeans(i, nstart = 20)
  km$tot.withinss
}
```

Note: writing function to be as general as possible, so that we can re-use it later.

Constructing within-cluster SS

Make a data frame with desired numbers of clusters, and fill it with the total within-group sums of squares. 'For each number of clusters, runss'', somap_dbl'.

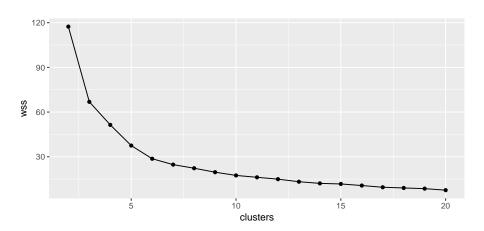

```
ssd <- tibble(clusters = 2:20) %>%
mutate(wss = map_dbl(clusters, ss, vital.s)) %>%
print(n = 10)
```

```
## # A tibble: 19 \times 2
##
      clusters
                  WSS
##
          <int> <dbl>
##
              2 117.
##
              3 66.9
              4 51.4
##
##
              5 37.5
    5
              6 28.7
##
                24.7
##
```

Lecture notes

Scree plot

```
ggplot(ssd, aes(x = clusters, y = wss)) + geom_point() +
  geom_line()
```

Interpreting scree plot

- Lower wss better.
- But lower for larger #clusters, harder to explain.
- Compromise: low-ish wss and low-ish #clusters.
- Look for "elbow" in plot.
- Idea: this is where wss decreases fast then slow.
- On our plot, small elbow at 6 clusters. Try this many clusters.

Six clusters, using nstart

```
vital.km6 <- vital.s %>%
  select(-4) %>%
  kmeans(6, nstart = 20)
vital.km6$size
```

```
## [1] 24 8 30 15 18 2
```

```
vital.km6$centers
```

```
##

##
##
    [9] "Columbia"
                                 "Venezuela"
## [11] "Bahrain"
                                 "United_Arab_Emirates"
## [13] "Hong_Kong"
                                 "Malaysia"
## [15] "Sri_Lanka"
```

Higher than average on everything, though not the highest:

```
get_countries(5, vital.6)
```

```
##
    [1] "Bolivia"
                       "Tran"
                                     "Bangladesh"
    Γ4]
##
        "Botswana"
                       "Gabon"
                                     "Ghana"
    [7] "Namibia"
##
                      "Swaziland"
                                     "Uganda"
   [10] "Zaire"
                       "Cambodia"
                                     "Nepal"
   [13] "Congo"
                       "Kenya"
                                     "Nigeria"
   [16] "Sudan"
                       "Tanzania"
                                     "Zambia"
```

Very high death rate, just below average on all else:

```
get_countries(6, vital.6)
```

```
## [1] "Mexico" "Korea"
```

Comparing our 3 and 6-cluster solutions

```
table(three = vital.km3$cluster, six = vital.km6$cluster)
```

```
## three 1 2 3 4 5 6
## 1 24 0 0 2 3 0
## 2 0 0 30 13 0 1
## 3 0 8 0 0 15 1
```

six

##

Compared to 3-cluster solution:

- most of cluster 1 gone to (new) cluster 1
- cluster 2 split into clusters 3 and 4 (two types of "richer" countries)
- cluster 3 split into clusters 2 and 5 (two types of "poor" countries, divided by death rate).
- cluster 6 (Mexico and Korea) was split before.

Getting a picture from kmeans

- Use multidimensional scaling (later)
- Use discriminant analysis on clusters found, treating them as "known" groups.

MANOVA and discriminant analysis

- Go back to 1st 3 columns of vital.s (variables, standardized), plus cf (cluster as factor). clus (6 clusters).
- First, do they actually differ by group? (MANOVA):

```
v \leftarrow vital.s \%\% select(-4) \%\% as.matrix()
cf <- as.factor(vital.km6$cluster)
vital.manova <- manova(v ~ cf)</pre>
summary(vital.manova)
```

15

273

```
##
            Df Pillai approx F num Df den Df
             5 1.9215 32.427

               Pr(>F)
##
## cf
            < 2.2e-16 ***
## Residuals
```

Discriminant analysis

- So what makes the groups different?
- Uses package MASS (loaded):

```
vital.lda <- lda(cf ~ birth + death + infant, data = vital.s)
vital.lda$svd</pre>
```

```
## [1] 21.687195 8.851811 1.773006
```

```
vital.lda$scaling
```

def

```
## LD1 LD2 LD3

## birth 2.6879695 1.1224202 1.9483853

## death 0.6652712 -2.7213044 0.6049358

## infant 2.1111801 0.7650912 -2.3542296
```

LD1 is some of everything, but not so much death rate (high=poor,

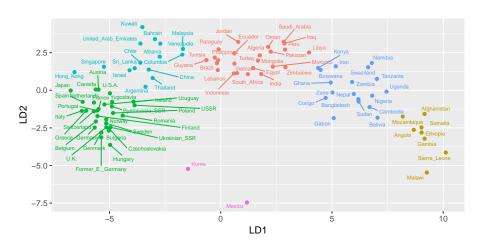

To make a plot

• Get predictions first:

```
vital.pred <- predict(vital.lda)</pre>
d <- data.frame(</pre>
  country = vital.s$country,
  cluster = vital.km6$cluster, vital.pred$x
glimpse(d)
## Observations: 97

             <dbl> -0.086392118, 0.067491502, -0.1...
```

The plot

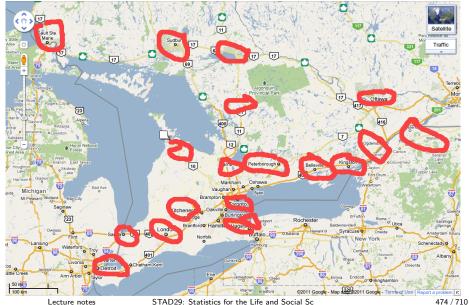

8

Final example: a hockey league

- An Ontario hockey league has teams in 21 cities. How can we arrange those teams into 4 geographical divisions?
- Distance data in spreadsheet.
- Take out spaces in team names.
- Save as "text/csv".
- Distances, so back to hclust.

A map

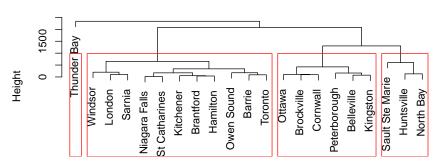

Attempt 1

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/ontario-ros
ontario <- read_csv(my_url)
ontario.d <- ontario %>% select(-1) %>% as.dist()
ontario.hc <- hclust(ontario.d, method = "ward.D")</pre>
```

Plot, with 4 clusters

```
plot(ontario.hc)
rect.hclust(ontario.hc, 4)
```

Cluster Dendrogram

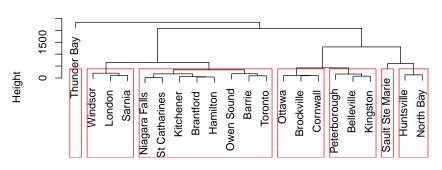

Comments

- Can't have divisions of 1 team!
- "Southern" divisions way too big!
- Try splitting into more. I found 7 to be good:

Seven clusters

```
plot(ontario.hc)
rect.hclust(ontario.hc, 7)
```

Cluster Dendrogram

Divisions now

- I want to put Huntsville and North Bay together with northern teams.
- I'll put the Eastern teams together. Gives:
- North: Sault Ste Marie, Sudbury, Huntsville, North Bay
- East: Brockville, Cornwall, Ottawa, Peterborough, Belleville, Kingston
- West: Windsor, London, Sarnia
- Central: Owen Sound, Barrie, Toronto, Niagara Falls, St Catharines, Brantford, Hamilton, Kitchener
- Getting them same size beyond us!

Another map

Section 11

Multidimensional scaling

Multidimensional Scaling

- Have distances between individuals.
- Want to draw a picture (map) in 2 dimensions showing individuals so that distances (or order of distances) as close together as possible. (Or maybe 3 with rgl.)
- If want to preserve actual distances, called {metric multidimensional scaling} (in R, cmdscale).
- If only want to preserve order of distances, called {non-metric multidimensional scaling} (in R, isoMDS in package MASS).
- Metric scaling has solution that can be worked out exactly.
- Non-metric only has iterative solution.
- Assess quality of fit, see whether use of resulting map is reasonable.
 (Try something obviously 3-dimensional and assess its failure.)

Packages

The usual, plus a new one:

```
library(MASS)
library(tidyverse)
```

```
## Warning: package 'ggplot2' was built under R
## version 3.5.3
```

```
## Warning: package 'tibble' was built under R

Multidimensional scaling

- Create distance object first using all but first column of europe.
 europe has distances in it already, so make into dist with as.dist.
- Then run multidimensional scaling and look at result:

```
europe.d <- europe %>% select(-1) %>% as.dist()
europe.scale <- cmdscale(europe.d)
head(europe.scale)</pre>
```

```
## [,1] [,2]
## Amsterdam -348.162277 528.2657
## Athens 2528.610410 -509.5208
## Barcelona -695.970779 -984.6093
## Berlin 384.178025 634.5239
## Cologne 5.153446 356.7230
## Copenhagen -187.104072 1142.5926
```

• This is a matrix of x and y coordinates.

As a data frame; make picture

We know how to plot data frames, so make one first.

```
europe_coord <- europe.scale %>%
  as tibble() %>%
  mutate(city = europe$City) %>%
  print(n = 12)
```

```
## Warning: `as_tibble.matrix()` requires a matrix with column
## This warning is displayed once per session.
```

Warning: Unknown or uninitialised column: 'City'.

3 -696. -985. STAD29: Statistics for the Life and Social Sc

The map

g

Error in FUN(X[[i]], ...): object 'city' not found

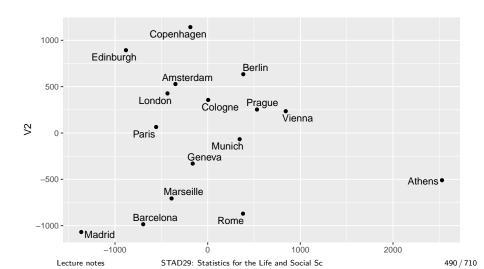

Making a function

 Idea: given input distance matrix (as stored in a CSV file), output a map (like the one on the previous page).

```
mds_map <- function(filename) {</pre>
  x <- read_csv(filename)
  dist <- x %>%
    select if(is.numeric) %>%
    as.dist()
  x.scale <- cmdscale(dist) # this is a matrix
  x coord <- x.scale %>%
    as tibble() %>%
    mutate(place = row.names(x.scale))
  ggplot(x coord, aes(x = V1, y = V2, label = place)) +
    geom point() + geom text repel() +
    coord fixed()
```

Does it work?

mds_map("europe.csv")

A square

```
The data, in square.csv: \begin{small}
```

```
x,A ,B ,C ,D
A,O ,1 ,1 ,1.4
B,1 ,O ,1.4,1
C,1 ,1.4,O ,1
D,1.4,1 ,1 ,O
\end{small}
```

\begin{multicols}{2}

The map (on right):

```
mds_map("square.csv")
```

Drawing a map of the real Europe

- Works with package ggmap.
- First find latitudes and longitudes of our cities, called *geocoding*:

```
latlong <- geocode(europe$City)
latlong <- bind_cols(city = europe$City, latlong)
latlong %>% print(n = 6)
```

STAD29: Statistics for the Life and Social Sc

Lecture notes

Making the map

 Get a map of Europe from Google Maps (specify what you want a map of any way you can in Google Maps). This one centres the map on the city shown and zooms it so all the cities appear (I had to experiment):

```
map <- get_map("Memmingen DE", zoom = 5)</pre>
```

 Plot the map with ggmap. This is ggplot, so add anything to it that you would add to a ggplot, such as cities we want to show:

```
g2 <- ggmap(map) +
  geom_point(
   data = latlong, aes(x = lon, y = lat),
   shape = 3, colour = "red"
)</pre>
```

 We don't have a default data frame or aes for our geom_point, so have to specify one.

The real Europe with our cities

g2

Compare our scaling map

Error in FUN(X[[i]], ...): object 'city' not found

Comments

- North-south not quite right: Edinburgh and Copenhagen on same latitude, also Amsterdam and Berlin; Athens should be south of Rome.
- Rotating clockwise by about 45 degrees should fix that.
- General point: MDS only uses distances, so answer can be "off" by rotation (as here) or reflection (flipping over, say exchanging west and east while leaving north and south same).

Exploring the map by plotting in 3 dimensions

- Package rgl makes 3D plots.
- We have to fake up a 3rd dimension (by setting all its values to 1).
- Try this code:

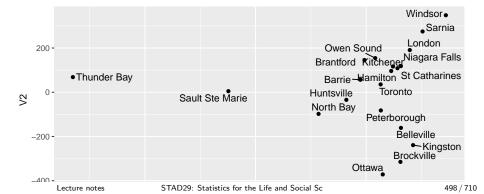

```
library(rgl)
es.2 <- cbind(europe.scale, 1)
plot3d(es.2, zlim = c(-1000, 1000))
text3d(es.2, text = d$city)</pre>
```

- Opens a graphics window with the cities plotted and named.
- Click and hold left mouse button to rotate plot. "Rotate away" 3rd dimension to get a possible map (that preserves distances).

Ontario, the same way

...using our function:

```
g <- mds_map("ontario-road-distances.csv")
g</pre>
```

Removing points

- Messy: have to find which rows and columns contain those cities, then remove just those rows and columns.
- Better:
- "tidy" the distance matrix
- then remove rows we don't need
- then "untidy" it again
- save into .csv file
- Illustrate with square data first (easier to see).

Square data

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/square.csv"
square <- read_csv(my_url)
square</pre>
```

Make tidy

```
square %>% gather(point, distance, -1)
```

```
## # A tibble: 16 x 3
##
             point distance
      <chr> <chr>

##
    9 A
   10 B
                         1.4
```

Lecture notes

Remove all references to point C

In column x or point:

```
square %>%
  gather(point, distance, -1) %>%
  filter(x != "C", point != "C")
## # A tibble: 9 \times 3
##
           point distance
     <chr> <chr>
##
                    <dbl>
## 1 A
## 2 B
## 3 D
                       1.4
## 4 A
## 5 B
```

1.4

STAD29: Statistics for the Life and Social Sc

Put back as distance matrix

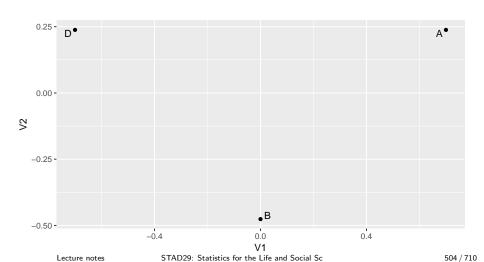

```
and save as .csv when we are happy:
```

```
noc <- square %>%
  gather(point, distance, -1) %>%
  filter(x != "C", point != "C") %>%
  spread(point, distance)
noc
```

```
## # A tibble: 3 x 4
## x A B D
## <chr> <dbl> <dbl> <dbl> <dbl> ## 1 A O 1 1.4
## 2 B 1 O 1
## 3 D 1.4 1 O
```

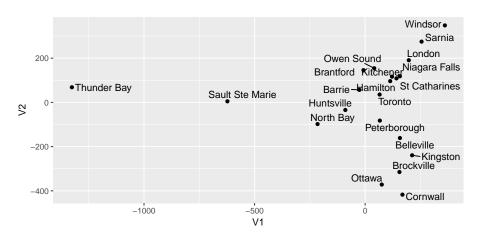

Make map of square-without-C

mds_map("no-c.csv")

Back to Ontario

g

Tidy, remove, untidy

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/ontario-ros
ontario2 <- read_csv(my_url) %>%
  gather(place, distance, -1) %>%
  filter(
    x != "Thunder Bay",
    place != "Thunder Bay",
    x != "Sault Ste Marie",
    place != "Sault Ste Marie"
) %>%
```

spread(place, distance) %>%
write_csv("southern-ontario.csv")

Lecture notes STAD29: Statistics for the Life and Social Sc 506/710

Map of Southern Ontario

```
g <- mds_map("southern-ontario.csv")
g</pre>
```

What about that cluster of points?

- Plot looks generally good, but what about that cluster of points?
- "Zoom in" on area between -150 and -100 on x axis, -50 to 0 on y axis.
- Code below overrides the coord fixed we had before.

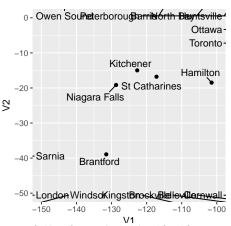

$$g2 \leftarrow g + coord_fixed(xlim = c(-150, -100), ylim = c(-50, 0))$$

Coordinate system already present. Adding new coordinate sy

Zoomed-in plot

Ignore the arrows to points off the map:

g2

Does that make sense?

- Get a Google map of the area, with the points labelled.
- First geocode the cities of interest:

```
cities <- c(
   "Kitchener ON", "Hamilton ON", "Niagara Falls ON",
   "St Catharines ON", "Brantford ON"
)
latlong <- geocode(cities)
latlong <- bind_cols(city = cities, latlong) %>% print()
```

STAD29: Statistics for the Life and Social Sc.

2 Hamilton ON -79.9 43.3 ## 3 Niagara Falls ON -79.1 43.1

A tibble: 5 x 3

Making the Google map

Plot the map, plus the cities, plus labels for the cities:

```
gmap \leftarrow ggmap(map) +
  geom_point(
    data = latlong,
    aes(x = lon, y = lat),
    shape = 3, colour = "red"
  ) +
  geom text repel(
    data = latlong,
    aes(label = city)
```

"'r g2 "' "'r gmap "'

\begin{frame}[frame]{The mds map and Google map}

```
![plot of chunk
```

Quality of fit

Read in "southern Ontario" data set from file:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/southern-or
ontario2 <- read_csv(my_url)</pre>
```

STAD29: Statistics for the Life and Social Sc.

Calling cmdscale with eig=T gives more info:

```
ontario2.2 <- ontario2 %>%
  select_if(is.numeric) %>%
  cmdscale(eig = T)
names(ontario2.2)
```

[1] "points" "eig" "x" "ac" "GOF"

ontario2.2\$GOF

```
## [1] 0.8381590 0.8914059 ontario2.3 <- ontario2 %>%
```

Comments

- Coordinates now in points.
- GOF is R-squared-like measure saying how well map distances match real ones. Higher is better.
- For Ontario road distances, GOF better for 3 dimensions than 2, presumably to accommodate St Catharines and Niagara Falls?

3-dimensional coordinates, cities attached

```
ontario2.3$points %>%
 as tibble() %>%
 mutate(city = ontario2$x)
## # A tibble: 19 \times 4
##
        V1
                V2
                        V3 city

Lecture notes

STAD29: Statistics for the Life and Social Sc

RGL code for 3 dimensions

```
library(rgl)
plot3d(ontario.3)
text3d(ontario.3, text = d2$city)
```

\begin{frame}[fragile]{Comparing MDS solution with "reality": Procrustes rotation}

- How to tell that an MDS map makes a good correspondence with "what should be"?
- Problem: MDS map might be rotated/scaled/reflected from reality.
- How to find rotation/scaling/reflection that best matches reality?
- Answer: Procrustes rotation.
- In R: procOPA in package shapes.

"True" coordinates

##

 Get latitudes and longitudes of cities by geocoding, as before. Glue "ON" onto city names to make sure we get right ones:

```
lookup <- str_c(ontario2$x, " ON")</pre>
latlong <- geocode(lookup)</pre>
latlong <- bind_cols(city = ontario2$x, latlong) %>% print(n =
## # A tibble: 19 \times 3
## city lon lat
```

3 Brantford -80.3 43.1 ## 4 Brockville -75.7 44.6 ## # ... with 15 more rows

Lecture notes

1 Barrie -79.7 44.4 ## 2 Belleville -77.4 44.2

<chr> <dbl> <dbl>

• Not (x,y) coordinates: one degree of latitude is always 110.25 km, but STAD29: Statistics for the Life and Social Sc

516 / 710

"True" coordinates part 2

- Make coordinates by multiplying by cosine of "typical" latitude.
- Find mean latitude:

```
m <- mean(latlong$lat)
m</pre>
```

- Turn into radians and find its cosine:
 - ult /- cos(m * ni / 190)

```
mult <- cos(m * pi / 180)
mult
```

[1] 0.7191153

[1] 44.01851

• Create "true" coords by multiplying the longitudes by that. This needs to be R matrix, not data frame:

```
truecoord <- with(latlong, cbind(V1 = lon * mult, V2 = lat))</pre>
```

Using procOPA

- Feed 2 things into procOPA: first, "true" coordinates, second MDS coordinates.
- Get out:
- (centred and scaled) first set of coordinates `Ahat`
- (centred and scaled) second set of coordinates Bhat
- sum of squared differences between two sets of coordinates OSS
- Rotation matrix R
- Ahat and Bhat coordinates supposed to match as well as possible.

```
ontario.pro <- procOPA(
  truecoord,
  ontario2.2$points
)</pre>
```

Make data frames of output, glue together

• Two sets of coordinates, Ahat are actual, Bhat are from MDS.

```
A <- ontario.pro$Ahat %>%
   as_tibble() %>%
   mutate(which = "actual", city = ontario2$x)
B <- ontario.pro$Bhat %>%
   as_tibble() %>%
   mutate(which = "MDS", city = ontario2$x)
dp <- bind_rows(A, B)
dp %>% sample_n(6)
```

```
## # A tibble: 6 x 4

## V1 V2 which city

## <dbl> <dbl> <chr> <chr>
## 1 2.39 0.348 MDS Brockville

## 2 0.000652 -0.929 actual Niagara Falls

## 3 -1.00 -0.568 actual Kitchener

Lecture notes STAD29: Statistics for the Life and Social Sc
```

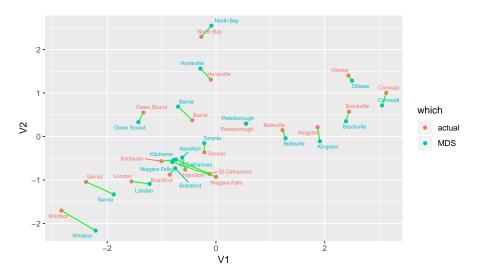

Procrustes rotation plot

- Strategy: plot all the locations, and colour them by whether they were the true location (red) or the MDS one (blue), which is in which. Label each location with the city name in the appropriate colour.
- I realized it was actually easy to join the two instances of a city by a line (in green, here, 3rd line) by setting group=city:

```
g_opa <- ggplot(dp, aes(
    x = V1, y = V2, colour = which,
    label = city
)) + geom_point() +
    geom_line(aes(group = city), colour = "green") +
    geom_text_repel(size = 2)</pre>
```

• On plot, look to see whether points that are same city are joined by a short green line (good) or a long one (bad).

The maps

Comments

- True locations red, MDS locations blue
- Most things in roughly right place (esp. relative to other things)
- Extreme cities off by a bit, but OK relative to neighbours.
- St Catharines, Niagara Falls off by most.
- Sarnia, Windsor also off noticeably.
- These four cities had largest "third dimension" in 3D representation ontario2.3.

Rotation matrix

Shows how MDS map needs to be rotated to get best match with actual coordinates:

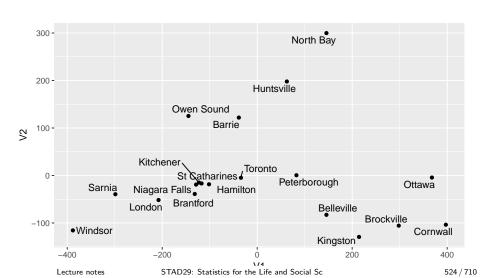

ontario.pro\$R

```
## [,1] [,2]
## [1,] 0.8845749 0.4663981
## [2,] -0.4663981 0.8845749
```

Rotation angle θ such that $\cos\theta=0.885$, $\sin\theta=0.466$: $\theta=23$ degrees (counterclockwise). \$ %\$ %\$

Is that right? Look at MDS map again

g

A cube

Cube has side length 1, so distance across diagonal on same face is $\sqrt{2} \simeq 1.4$ and "long" diagonal of cube is $\sqrt{3} \simeq 1.7$.

Try MDS on this obviously 3-dimensional data.

Cube data as distances

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/cube.txt"
cube <- read_delim(my_url, " ")
cube</pre>
```

```
A tibble: 8 x 9

```

##

MDS and plotting commands

By default in 2 dimensions; save the extra stuff for later:

```
cube.2 <- cube.d %>% cmdscale(eig = T)
```

 Make data frame to plot, remembering the points to plot are in points now:

```
d <- cube.2$points %>%
  as_tibble() %>%
  mutate(corners = cube$x)
```

• Plot points labelled by our names for the corners:

```
g <- ggplot(d, aes(x = V1, y = V2, label = corners)) +
  geom_point() + geom_text_repel()</pre>
```

The "cube"

Lecture notes

2 and 3 dimensions

```
cube.3 <- cube.d %>% cmdscale(3, eig = T)
cube.2$GOF
```

```
## [1] 0.639293 0.664332
```

```
cube.3$GOF
```

```
## [1] 0.9143532 0.9501654
```

Really need 3rd dimension to represent cube.

Non-metric scaling

- Sometimes distances not meaningful as distances
- Only order matters: closest should be closest, farthest farthest on map, but how much further doesn't matter.
- Non-metric scaling, aims to minimize stress, measure of lack of fit.
- Example: languages. Make map based on "similarity" of number names, without requiring that 1 is "eight times better" than 8.

The languages

Lecture notes

number.d <- read_table(my_url)</pre>

 Recall language data (from cluster analysis): 1–10, measure dissimilarity between two languages by how many number names {differ} in first letter:

my_url <- "http://www.utsc.utoronto.ca/~butler/d29/languages.t

```
number.d

```

STAD29: Statistics for the Life and Social Sc

532 / 710

Non-metric scaling

- Turn language dissimilarities into dist object
- Run through isoMDS from MASS package; works like cmdscale.
- Map only reproduces {relative} closeness of languages.

```
d <- number.d %>%
    select_if(is.numeric) %>%
    as.dist()
number.nm <- d %>% isoMDS()

## initial value 12.404671
## iter 5 value 5.933653
## iter 10 value 5.300747
## final value 5.265236
## converged
```

names(number.nm)

Results

• Stress is very low (5%, good):

```
number.nm$stress
```

```
## [1] 5.265236
$ %$ %$
```

 Familiar process: make a data frame to plot. Use name dd for data frame this time since used d for distance object:

```
dd <- number.nm$points %>%
  as_tibble() %>%
  mutate(lang = number.d$la)
```

Make plot:

```
g <- ggplot(dd, aes(x = V1, y = V2, label = lang)) +
geom_point() + geom_text_repel()</pre>
```

The languages map

Comments

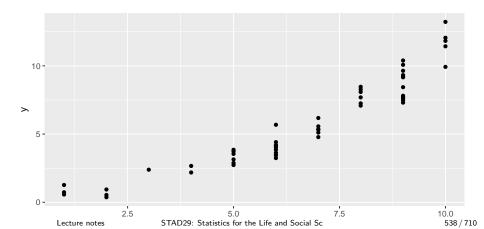

- Tight clusters: Italian-Spanish-French, English-Danish-Norwegian.
- Dutch and German close to English group.
- Polish close to French group.
- Hungarian, Finnish distant from everything else and each other!
- Similar conclusions as from the cluster analysis.

Shepard diagram

- Stress for languages data was 5.3%, very low.
- How do observed dissimilarities and map distances correspond?
- For low stress, expect larger dissimilarity to go with larger map distance, almost all the time.
- Not necessarily a linear trend since non-metric MDS works with order of values.
- Actual dissimilarity on x-axis; map distances on y-axis.

Shepard diagram for languages

```
Shepard(d, number.nm$points) %>%
  as_tibble() %>%
  ggplot(aes(x = x, y = y)) + geom_point()
```

Cube, revisited

by coercion

```
cube.d <- cube %>% select(-x) %>% as.dist(cube)

## Warning in storage.mode(m) <- "numeric": NAs introduced</pre>
```

STAD29: Statistics for the Life and Social Sc.

```
cube.2 <- isoMDS(cube.d, trace = F)
cube.2$stress</pre>
```

```
## [1] 17.97392
```

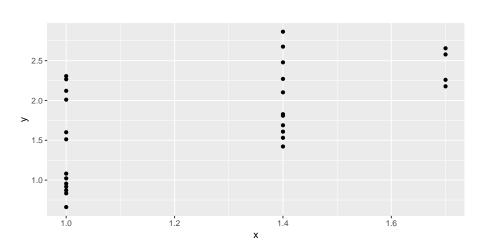

```
cube.3 <- isoMDS(cube.d, k = 3, trace = F)
cube.3$stress</pre>
```

```
## [1] 0.007819523
```

- Stress is 18% for 2 dimensions, basically 0% for 3.
- Three dimensions correct, two dimensions bad.
- Shepard diagrams for these: Lecture notes STAD29: Stat

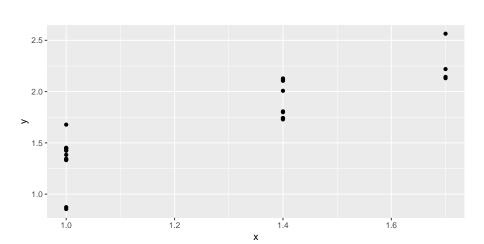

Shepard diagram for 2-dimensional cube

g2

Shepard diagram for 3-dimensional cube

g3

Guidelines for stress values, in %

Smaller is better:

Stress value	Interpretation
Less than 5	Excellent: no prospect of misinterpretation
	(rarely achieved)
5–10	Good: most distances reproduced well, small
	prospect of false inferences
10-20	Fair: usable, but some distances misleading.
More than 20	Poor: may be dangerous to interpret

- Languages: stress in "good" range.
- Cube:
- 2 dimensions "fair", almost "poor";
- 3 dimensions, "excellent". «echo=F, warning=F»= pkgs = names(sessionInfo()\$otherPkgs) pkgs=paste('package:', pkgs, sep = "") x=lapply(pkgs, detach, character.only = TRUE, unload = TRUE)

Section 12

Principal components

Principal Components

- Have measurements on (possibly large) number of variables on some individuals.
- Question: can we describe data using fewer variables (because original variables correlated in some way)?
- Look for direction (linear combination of original variables) in which values {most spread out}. This is {first principal component}.
- Second principal component then direction uncorrelated with this in which values then most spread out. And so on.

Principal components

- See whether small number of principal components captures most of variation in data.
- Might try to interpret principal components.
- If 2 components good, can make plot of data.
- (Like discriminant analysis, but no groups.)
- "What are important ways that these data vary?"

Packages

```
## Warning: package 'ggbiplot' was built under R version
## 3.5.1

## Warning: package 'scales' was built under R version
## 3.5.1

You might not have installed the first of these. See over for instructions.

library(ggbiplot) # see over
library(tidyverse)
library(ggrepel)
```

Warning: package 'plyr' was built under R version 3.5.1

Installing ggbiplot

- ggbiplot not on CRAN, so usual install.packages will not work.
- Install package devtools first (once):

```
install.packages("devtools")
```

Then install ggbiplot (once):

```
library(devtools)
install_github("vqv/ggbiplot")
```

Small example: 2 test scores for 8 people

```
my url <- "http://www.utsc.utoronto.ca/~butler/d29/test12.txt"
test12 <- read_table2(my_url)</pre>
test12
## # A tibble: 8 x 3
##
    first second id
##
    <dbl> <dbl> <chr>
## 1
       2
               9 A
    16 40 B
## 2
## 3
    8
            17 C
    18 43 D
## 4
```

7 10 27 G 12 30 H ## 8 g <- ggplot(test12, aes(x = first, y = second, label = id)) +

10 25 E

Lecture notes

10 F

The plot

Principal component analysis

• Grab just the numeric columns:

```
test12_numbers <- test12 %>% select_if(is.numeric)
```

Strongly correlated, so data nearly 1-dimensional:

```
cor(test12 numbers)
```

```
##
            first second
## first 1.000000 0.989078
## second 0.989078 1.000000
```

• Make a score summarizing this one dimension. Like this:

```
test12.pc <- test12 numbers %>% princomp(cor = T)
summary(test12.pc)
```

```
Importance of components:
```

##

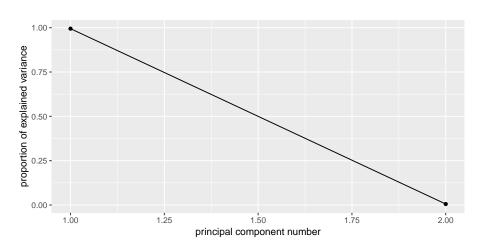

Comp. 1 Lecture notes

Comments

- "Standard deviation" shows relative importance of components (as for LDs in discriminant analysis)
- Here, first one explains almost all (99.4%) of variability.
- That is, look only at first component and ignore second.
- cor=T standardizes all variables first. Usually wanted, because variables measured on different scales. (Only omit if variables measured on same scale and expect similar variability.)

Scree plot

ggscreeplot(test12.pc)

Component loadings

explain how each principal component depends on (standardized) original variables (test scores):

```
test12.pc$loadings
```

Lecture notes

```
##
  Loadings:
##
         Comp.1 Comp.2
## first 0.707 0.707
## second 0.707 -0.707
##
##
                Comp.1 Comp.2
## SS loadings
                   1.0 1.0
  Proportion Var 0.5 0.5
## Cumulative Var 0.5 1.0
```

First component basically negative sum of (standardized) test scores. That STAD29: Statistics for the Life and Social Sc 553 / 710

## 8
               30
$
```

- Person A is a low scorer, high positive comp.1 score.
- Person D is high scorer, high negative comp.1 score.

Plot of scores

```
ggplot(d, aes(x = Comp.1, y = Comp.2, label = id)) +
  geom_point() + geom_text_repel()
```

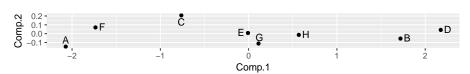

Comments

- Vertical scale exaggerates importance of comp.2.
- Fix up to get axes on same scale:

```
g <- ggplot(d, aes(x = Comp.1, y = Comp.2, label = id)) +
  geom_point() + geom_text_repel() +
  coord_fixed()</pre>
```

Shows how exam scores really spread out along one dimension:

g

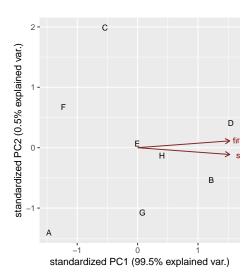

The biplot

- Plotting variables and individuals on one plot.
- Shows how components and original variables related.
- Shows how individuals score on each component, and therefore suggests how they score on each variable.
- Add labels option to identify individuals:

```
g <- ggbiplot(test12.pc, labels = test12$id)
```

The biplot

Comments

- Variables point almost same direction (left). Thus very negative value on comp.1 goes with high scores on both tests, and test scores highly correlated.
- Position of individuals on plot according to scores on principal components, implies values on original variables. Eg.:
- D very negative on comp.1, high scorer on both tests.
- A and F very positive on comp.1, poor scorers on both tests.
- C positive on comp.2, high score on first test relative to second.
- A negative on comp.2, high score on second test relative to first.

Track running data

A tibble: 12×9

Lecture notes

(1984) track running records for distances 100m to marathon, arranged by country. Countries labelled by (mostly) Internet domain names (ISO 2-letter codes):

```
my url <- "http://www.utsc.utoronto.ca/~butler/d29/men_track_:
track <- read_table(my_url)</pre>
track %>% sample_n(12)
```

```

Data and aims

- Times in seconds 100m-400m, in minutes for rest (800m up).
- This taken care of by standardization.
- 8 variables; can we summarize by fewer and gain some insight?
- In particular, if 2 components tell most of story, what do we see in a plot?

Fit and examine principal components

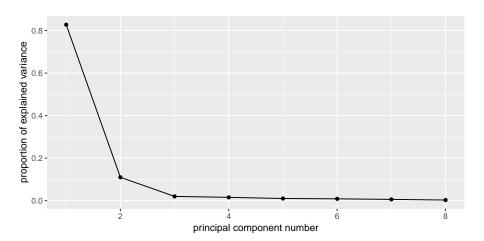

Lecture notes

```
track num <- track %>% select if(is.numeric)
track.pc <- princomp(track_num, cor = T)</pre>
summary(track.pc)

STAD29: Statistics for the Life and Social Sc.

Scree plot

ggscreeplot(track.pc)

How many components?

- As for discriminant analysis, look for "elbow" in scree plot.
- See one here at 3 components; everything 3 and beyond is "scree".
- So take 2 components.
- Note difference from discriminant analysis: want "large" rather than "small", so go 1 step left of elbow.
- Another criterion: any component with eigenvalue bigger than about 1 is worth including. 2nd one here has eigenvalue just less than 1.
- Refer back to summary: cumulative proportion of variance explained for 2 components is 93.7%, pleasantly high. 2 components tell almost whole story.

How do components depend on original variables?

```

Comments

- comp.1 loads about equally (has equal weight) on times over all distances.
- comp.2 has large positive loading for long distances, large negative for short ones.
- comp.3: large negative for middle distance, large positive especially for short distances.
- Country overall good at running will have lower than average record times at all distances, so comp.1 large. Conversely, for countries bad at running, comp.1 very negative.
- Countries relatively better at sprinting (low times) will be positive on comp.2; countries relatively better at distance running negative on comp.2.

Commands for plots

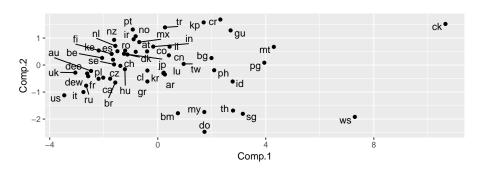

• Principal component scores (first two). Also need country names.

```
d <- data.frame(track.pc$scores,</pre>
  country = track$country
names(d)
## [1] "Comp.1" "Comp.2" "Comp.3"
                                      "Comp.4" "Comp.5"
## [6] "Comp.6" "Comp.7" "Comp.8"
                                      "country"
g1 <- ggplot(d, aes(
  x = Comp.1, y = Comp.2,
  label = country
)) +
  geom_point() + geom_text_repel() +
  coord_fixed()
```

Biplot: Lecture notes

Principal components plot

g1

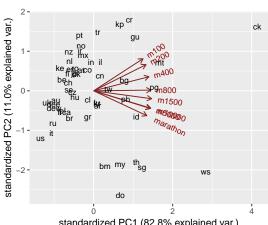

Comments on principal components plot

- Good running countries at right of plot: US, UK, Italy, Russia, East and West Germany.
- Bad running countries at left: Western Samoa, Cook Islands.
- Better sprinting countries at bottom: US, Italy, Russia, Brazil, Greece.
 do is Dominican Republic, where sprinting records relatively good,
 distance records very bad.
- Better distance-running countries at top: Portugal, Norway, Turkey, Ireland, New Zealand, Mexico. ke is Kenya.

Biplot

g2

standardized PC1 (82.8% explained var.)

Comments on biplot

- Had to do some pre-work to interpret PC plot. Biplot more self-contained.
- All variable arrows point left; countries on left have large (bad) record times overall, countries on right good overall.
- Variable arrows extend negatively as well. Top left = bad at distance running, bottom right = good at distance running.
- Bottom left = bad at sprinting, top right = good at sprinting.
- Doesn't require so much pre-interpretation of components.

How do I know which country is which?

Need to look up two-letter abbreviations in ISO table, eg. for best 8 running countries:

```
d %>%
  arrange(desc(Comp.1)) %>%
  left_join(iso, by = c("country" = "ISO2")) %>%
  select(Comp.1, country, Country) %>%
  slice(1:8)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict prefer()`
## * conflict_prefer("arrange", "plyr")
## * conflict prefer("arrange", "dplyr")
```

Best 8 running countries

d %>%

```
arrange(Comp.1) %>%
  left_join(iso, by = c("country" = "ISO2")) %>%
  select(Comp.1, country, Country) %>%
  slice(1:8)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict prefer()`
## * conflict prefer("arrange", "plyr")
## * conflict prefer("arrange", "dplyr")
```

Worst 8 running countries

```
d %>%
  arrange(desc(Comp.1)) %>%
  left_join(iso, by = c("country" = "ISO2")) %>%
  select(Comp.1, country, Country) %>%
  slice(1:8)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict prefer()`
## * conflict prefer("arrange", "plyr")
## * conflict prefer("arrange", "dplyr")
```

Better at distance running

d %>%

```
arrange(desc(Comp.2)) %>%
  left_join(iso, by = c("country" = "ISO2")) %>%
  select(Comp.2, country, Country) %>%
  slice(1:8)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict prefer()`
## * conflict prefer("arrange", "plyr")
## * conflict prefer("arrange", "dplyr")
```

Better at sprinting

```
d %>%
  arrange(Comp.2) %>%
  left_join(iso, by = c("country" = "ISO2")) %>%
  select(Comp.2, country, Country) %>%
  slice(1:10)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * plyr::arrange
## * dplyr::arrange
## Or declare a preference with `conflict prefer()`
## * conflict prefer("arrange", "plyr")
```

* conflict prefer("arrange", "dplyr")

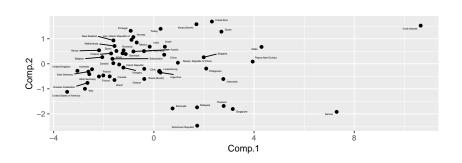

Plot with country names

```
g <- d %>%
  left_join(iso, by = c("country" = "ISO2")) %>%
  select(Comp.1, Comp.2, Country) %>%
  ggplot(aes(x = Comp.1, y = Comp.2, label = Country)) +
  geom_point() + geom_text_repel(size = 1) +
  coord_fixed()
```

Warning: Column `country`/`ISO2` joining factor and
character vector, coercing into character vector

The plot

g

Principal components from correlation matrix

Create data file like this: cov.txt and read in like this:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/cov.txt"
mat <- read_table(my_url, col_names = F)
mat</pre>
```

```
## # A tibble: 3 x 3
## X1 X2 X3
## <dbl> <dbl> <dbl> <dbl> = 0.970 -0.96
## 2 0.970 1 -0.998
## 3 -0.96 -0.998 1
```

Pre-processing

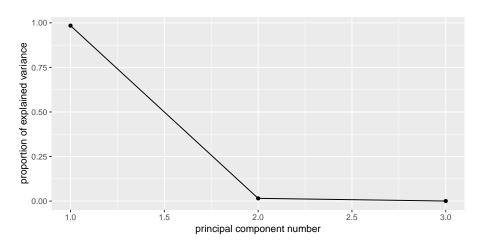

A little pre-processing required:

- Turn into matrix (from data frame)
- Feed into princomp as covmat=

```
mat.pc <- mat %>%
  as.matrix() %>%
  princomp(covmat = .)
```

Scree plot: one component fine

ggscreeplot(mat.pc)

Component loadings

Compare correlation matrix:

"'r mat "'

```
A tibble: 3 x 3 X1 X2 X3 <dbl> * Then 'comp.1' *negative*.
<dbl> 1 1 0.970 -0.96 2 0.970 1 -0.998 3 * When X1 small, X2 small,
-0.96 -0.998 1 "'
with component loadings
"'r mat.pcloadings"
    Loadings: Comp.1 Comp.2 Comp.3 X1
0.573 0.812 0.112 X2 0.581 -0.306 -0.755 X3
-0.578 0.498 -0.646 Comp.1 Comp.2 Comp.3
SS loadings 1.000 1.000 1.000 Proportion
Var 0.333 0.333 0.333 Cumulative Var 0.333
0.667 1.000 ""
```

- * When X1 large, X2 also large, X3 small.
- X3 large.
 - * Then 'comp.1' *positive*.

No scores

- With correlation matrix rather than data, no component scores
- So no principal component plot
- and no biplot.

Section 13

Exploratory factor analysis

Principal components and factor analysis

- Principal components:
- Purely mathematical.
- Find eigenvalues, eigenvectors of correlation matrix.
- No testing whether observed components reproducible, or even probability model behind it.
- Factor analysis:
- some way towards fixing this (get test of appropriateness)
- In factor analysis, each variable modelled as: "common factor" (eg. verbal ability) and "specific factor" (left over).
- Choose the common factors to "best" reproduce pattern seen in correlation matrix.
- Iterative procedure, different answer from principal components.

Packages

```
library(lavaan) # for confirmatory, later
library(ggbiplot)
library(tidyverse)
```

Example

- 145 children given 5 tests, called PARA, SENT, WORD, ADD and DOTS. 3 linguistic tasks (paragraph comprehension, sentence completion and word meaning), 2 mathematical ones (addition and counting dots).
- Correlation matrix of scores on the tests:

```
para 1 0.722 0.714 0.203 0.095 sent 0.722 1 0.685 0.246 0.181 word 0.714 0.685 1 0.170 0.113 add 0.203 0.246 0.170 1 0.585 dots 0.095 0.181 0.113 0.585 1
```

• Is there small number of underlying "constructs" (unobservable) that explains this pattern of correlations?

To start: principal components

Using correlation matrix:

A tibble: 5 x 6

kids.pc <- kids %>%

as.matrix() %>%

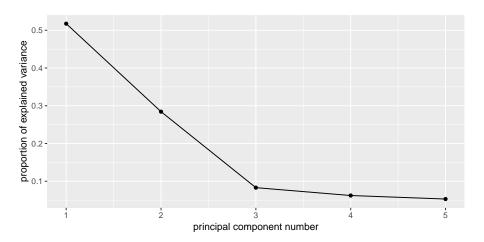

select if(is.numeric) %>%

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/rex2.txt"
kids <- read_delim(my_url, " ")
kids</pre>
```

test para sent word add dots

Scree plot

ggscreeplot(kids.pc)

Principal component results

Need 2 components. Loadings:

```
kids.pc$loadings
```

```
##
## Loadings:
##
       Comp.1 Comp.2 Comp.3 Comp.4 Comp.5
## para 0.534 0.245 0.114
                                  0.795
## sent 0.542 0.164 0.660 -0.489

## add 0.297 -0.627 0.707
## dots 0.241 -0.678 -0.680
                                  0.143
##
##
                Comp.1 Comp.2 Comp.3 Comp.4 Comp.5
  SS loadings
                   1.0 1.0 1.0 1.0
                                              1.0
## Proportion Var 0.2 0.2 0.2 0.2 0.2
  Cumulative Var 0.2
                          0.4
                                0.6
                                       0.8
                                              1.0
     Lecture notes
                 STAD29: Statistics for the Life and Social Sc.
```

Factor analysis

- Specify number of factors first, get solution with exactly that many factors.
- Includes hypothesis test, need to specify how many children wrote the tests.
- Works from correlation matrix via covmat or actual data, like princomp.
- Introduces extra feature, *rotation*, to make interpretation of loadings (factor-variable relation) easier.

Factor analysis for the kids data

- Create "covariance list" to include number of children who wrote the tests.
- Feed this into factanal, specifying how many factors (2).

```
km <- kids %>%
  select_if(is.numeric) %>%
  as.matrix()
km2 <- list(cov = km, n.obs = 145)
kids.f2 <- factanal(factors = 2, covmat = km2)</pre>
```

Uniquenesses

kids.f2\$uniquenesses

```
## para sent word add dots
## 0.2424457 0.2997349 0.3272312 0.5743568 0.1554076
$
```

- Uniquenesses say how "unique" a variable is (size of specific factor).
 Small uniqueness means that the variable is summarized by a factor (good).
- Mildly worried by how large add's uniqueness is.
- Also see "communality" for this, where large is good.

Loadings

```
"'r kids.f2loadings" * Loadings show how each "' Loadings: Factor1 Factor2 [1,] 0.867 factor depends on variables. [2,] 0.820 0.166 [3,] 0.816 [4,] 0.167 0.631 Blanks indicate "small", less [5,] 0.918 Factor1 Factor2 SS loadings than 0.1. 2.119 1.282 Proportion Var 0.424 0.256 * Factor 1 clearly the "linguis-Cumulative Var 0.424 0.680 "' tic" tasks, factor 2 clearly the "mathematical" ones. * Two factors together explain
```

68% of variability (like regres-

sion R-squared).

Are 2 factors enough?

```
kids.f2$STATISTIC
## objective
## 0.5810578
kids.f2$dof
## [1] 1
kids.f2$PVAL
   objective
```

P-value not small, so 2 factors OK.

0.445898

1 factor

##

```
kids.f1 <- factanal(factors = 1, covmat = km2)
kids.f1$STATISTIC

## objective
## 58.16534
kids.f1$dof

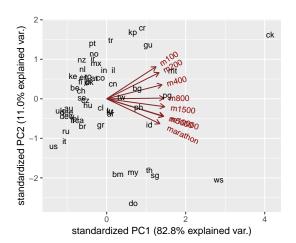

## [1] 5
kids.f1$PVAL</pre>
```

```
## 2.907856e-11
1 factor rejected (P-value small). Definitely need more than 1.
```

objective

Track running records revisited

g2

Benefit of rotation

- 100m and marathon arrows almost perpendicular, but components don't match anything much:
- sprinting: top left and bottom right
- distance running: bottom left and top right.
- Can we arrange things so that components (factors) correspond to something meaningful?

Track records by factor analysis

Obtain factor scores (have actual data):

A tibble: 55×9

```

Track data biplot

Not so nice-looking:

```
biplot(track.f$scores, track.f$loadings,
   xlabs = track$country
)
```

Comments

- This time 100m "up" (factor 2), marathon "right" (factor 1).
- Countries most negative on factor 2 good at sprinting.
- Countries most negative on factor 1 good at distance running.

Rotated factor loadings

```

A bigger example: BEM sex role inventory

- 369 women asked to rate themselves on 60 traits, like "self-reliant" or "shy".
- Rating 1 "never or almost never true of me" to 7 "always or almost always true of me".
- 60 personality traits is a lot. Can we find a smaller number of factors that capture aspects of personality?
- The whole BEM sex role inventory on next page.

The whole inventory

 self reliant 21.reliable 41.warm 2. yielding 22.analytical 42.solemn helpful 23.sympathetic 43. willing to take a stand defends own 24.jealous 44.tender beliefs 25.leadership ability 45.friendly cheerful 26 sensitive to other's needs 46.aggressive 27.truthful 47.gullible moody independent 28.willing to take risks 48.inefficient 49.acts as a leader shy 29.understanding 9. conscientious 30.secretive 50.childlike 10.athletic 31.makes decisions easily 51.adaptable 52.individualistic 11.affectionate 32.compassionate 12.theatrical 33.sincere 53.does not use harsh 34.self-sufficient 13.assertive language 14.flatterable 35.eager to soothe hurt 54.unsystematic feelings 55.competitive 15.happy 56 loves children 16.strong personality 36.conceited 17.loyal 37.dominant 57.tactful 18.unpredictable 38.soft spoken 58.ambitious 19 forceful 39.likable 59.gentle 20.feminine 40.masculine 60 conventional

       Lecture notes
```

Comments

- Want overall fraction of variance explained ("cumulative proportion") to be reasonably high.
- 2 factors, 28.5%. Terrible!
- Even 56% (10 factors) not that good!
- Have to live with that.

Biplot

ggbiplot(bem.pc, alpha = 0.3)

Comments

- Ignore individuals for now.
- Most variables point to 10 o'clock or 7 o'clock.
- Suggests factor analysis with rotation will get interpretable factors (rotate to 6 o'clock and 9 o'clock, for example).
- Try for 2-factor solution (rough interpretation, will be bad):

```
bem.2 <- bem %>%
select(-subno) %>%
factanal(factors = 2)
```

• Show output in pieces (just print bem.2 to see all of it).

Making a data frame

There are too many to read easily, so make a data frame. This is a bit tricky:

```
loadings <- as.data.frame(unclass(bem.2$loadings)) %>%
mutate(trait = rownames(bem.2$loadings))
```

```
## Either pick the one you want with `::`
## * dplyr::mutate
## * plyr::mutate
```

Or declare a preference with `conflict_prefer()`

[conflicted] `mutate` found in 2 packages.

* conflict_prefer("mutate", "dplyr")
* conflict_prefer("mutate", "plyr")

```
loadings %>% slice(1:10)
```

Error in UseMethod("slice_"): no applicable method for 'sl:

Pick out the big ones on factor 1

```
Arbitrarily defining > 0.4 or < -0.4 as "big": loadings %>% filter(abs(Factor1) > 0.4)
```

```

```

Factor 2, the big ones

```
loadings %>% filter(abs(Factor2) > 0.4)
```

Error in UseMethod("filter_"): no applicable method for 'f:

Plotting the two factors

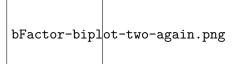

A bi-plot, this time with the variables reduced in size. Looking for unusual individuals.

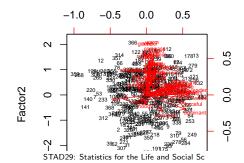

Have to run factanal again to get factor scores for plotting.

```
bem.2a <- factanal(bem[, -1], factors = 2, scores = "r")
biplot(bem.2a\$scores, bem.2a\$loadings, cex = c(0.5, 0.5))
```

Numbers on plot are row numbers of bem data frame.

The (awful) biplot

Comments

- Variables mostly up ("feminine") and right ("masculine"), accomplished by rotation.
- Some unusual individuals: 311, 214 (low on factor 2), 366 (high on factor 2), 359, 258 (low on factor 1), 230 (high on factor 1).

Individual 366

 $\begin{multicols}{2}$

bem %>% slice(366) %>% glimpse()

```
Observations: 1
## Variables: 45
## $ subno <dbl> 755
  $ helpful <dbl> 7
## $ reliant <dbl> 7
## $ defbel
              <dbl> 5
  $ yielding <dbl> 7
  $ cheerful
              <dbl> 7
              <dbl> 7
## $ indpt
## $ athlet <dbl> 7
  $ shy
              <dbl> 2
## $ assert <dbl> 1
              \langle db1 \rangle 3
     strpers
```

Lecture notes

Tidying original data

```
bem tidy <- bem %>%
  mutate(row = row number()) %>%
  gather(trait, score, c(-subno, -row))
## [conflicted] `mutate` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::mutate
## * plyr::mutate
## Or declare a preference with `conflict prefer()`
## * conflict_prefer("mutate", "dplyr")
## * conflict_prefer("mutate", "plyr")
bem_tidy
```

Error in eval(expr, envir, enclos): object 'bem_tidy' not :

Recall data frame of loadings

```
loadings %>% slice(1:10)
```

Error in UseMethod("slice_"): no applicable method for 'sl:

Want to add the factor scores for each trait to our tidy data frame bem_tidy. This is a left-join (over), matching on the column trait that is in both data frames (thus, the default):

Looking up loadings

```
bem_tidy <- bem_tidy %>% left_join(loadings)

## Error in eval(lhs, parent, parent): object 'bem_tidy' not :
bem_tidy %>% sample_n(12)
```

Error in eval(lhs, parent, parent): object 'bem_tidy' not :

Individual 366, high on Factor 2

So now pick out the rows of the tidy data frame that belong to individual 366 (row=366) and for which the Factor2 score exceeds 0.4 in absolute value (our "big" from before):

```
bem_tidy %>% filter(row == 366, abs(Factor2) > 0.4)
```

```
## Error in eval(lhs, parent, parent): object 'bem_tidy' not :
As expected, high scorer on these.
```

Several individuals

Rows 311 and 214 were *low* on Factor 2, so their scores should be low. Can we do them all at once?

```
bem_tidy %>% filter(
  row %in% c(366, 311, 214),
  abs(Factor2) > 0.4
)
```

```
## Error in eval(lhs, parent, parent): object 'bem_tidy' not :
```

Can we display each individual in own column?

Individual by column

Un-tidy, that is, spread:

```
bem_tidy %>%
  filter(
    row %in% c(366, 311, 214),
    abs(Factor2) > 0.4
) %>%
  select(-subno, -Factor1, -Factor2) %>%
  spread(row, score)
```

```
## Error in eval(lhs, parent, parent): object 'bem_tidy' not in 366 high, 311 middling, 214 (sometimes) low.
```

Individuals 230, 258, 359

These were high, low, low on factor 1. Adapt code:

```
bem_tidy %>%
  filter(row %in% c(359, 258, 230), abs(Factor1) > 0.4) %>%
  select(-subno, -Factor1, -Factor2) %>%
  spread(row, score)
```

```
## Error in eval(lhs, parent, parent): object 'bem_tidy' not :
```

Is 2 factors enough?

```
Suspect not: bem.2$PVAL
```

```
## objective
## 1.458183e-150
```

 $2\ \mbox{factors}$ resoundingly rejected. Need more. Have to go all the way to $15\ \mbox{factors}$ to not reject:

```
bem.15 <- bem %>%
  select(-subno) %>%
  factanal(factors = 15)
bem.15$PVAL
```

```
## objective
## 0.132617
```

Even then, only just over 50% of variability explained.

Lecture notes STAD29: Statistics for the Life and Social Sc

Get factor loadings

into a data frame, as before:

```
loadings <- as.data.frame(unclass(bem.15$loadings)) %>%
mutate(trait = rownames(bem.15$loadings))
```

```
## [conflicted] `mutate` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::mutate
## * plyr::mutate
## Or declare a preference with `conflict_prefer()`
## * conflict_prefer("mutate", "dplyr")
## * conflict_prefer("mutate", "plyr")
```

then show the highest few loadings on each factor.

```
loadings %>%
  arrange(desc(abs(Factor1))) %>%
  select(Factor1, trait) %>%
  slice(1:10)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::arrange
## * plyr::arrange
## Or declare a preference with `conflict_prefer()`
## * conflict_prefer("arrange", "dplyr")
## * conflict_prefer("arrange", "plyr")
```

Compassionate, understanding, sympathetic, soothing: thoughtful of others.

```
loadings %>%
  arrange(desc(abs(Factor2))) %>%
  select(Factor2, trait) %>%
  slice(1:10)

## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::arrange
```

Strong personality, forceful, assertive, dominant: getting ahead.

Or declare a preference with `conflict_prefer()`

* conflict_prefer("arrange", "dplyr")
* conflict_prefer("arrange", "plyr")

* plyr::arrange

```
loadings %>%
  arrange(desc(abs(Factor3))) %>%
  select(Factor3, trait) %>%
  slice(1:10)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::arrange
## * plyr::arrange
## Or declare a preference with `conflict_prefer()`
## * conflict_prefer("arrange", "dplyr")
## * conflict_prefer("arrange", "plyr")
```

Self-reliant, self-sufficient, independent: going it alone.

```
loadings %>%
  arrange(desc(abs(Factor4))) %>%
  select(Factor4, trait) %>%
  slice(1:10)
## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::arrange
## * plyr::arrange
## Or declare a preference with `conflict_prefer()`
## * conflict prefer("arrange", "dplyr")
## * conflict_prefer("arrange", "plyr")
```

Gentle, tender, warm (affectionate): caring for others.

```
loadings %>%
  arrange(desc(abs(Factor5))) %>%
  select(Factor5, trait) %>%
  slice(1:10)

## [conflicted] `arrange` found in 2 packages.
## Either pick the one you want with `::`
## * dplyr::arrange
```

Ambitious, competitive (with a bit of risk-taking and individualism): Being the best.

Or declare a preference with `conflict_prefer()`

* conflict_prefer("arrange", "dplyr")
* conflict_prefer("arrange", "plyr")

* plyr::arrange

```
loadings %>%

## * dplyr::arrange
## * plyr::arrange
## Or declare a preference with `conflict_prefer()`
## * conflict_prefer("arrange", "dplyr")
## * conflict_prefer("arrange", "plyr")
```

Uses foul language especially, also loves children and analytical. So could use even more factors.

Confirmatory factor analysis}

Section 14

Confirmatory factor analysis}

Confirmatory factor analysis

- Exploratory: what do data suggest as hidden underlying factors (in terms of variables observed)?
- Confirmatory: have {theory} about how underlying factors depend on observed variables; test whether theory supported by data:
- does theory provide {some} explanation (better than nothing)
- can we do better?
- Also can compare two theories about factors: is more complicated one significantly better than simpler one?

Children and tests again

Previously had this correlation matrix of test scores (based on 145 children):

```
km
```

```
## para sent word add dots
## [1,] 1.000 0.722 0.714 0.203 0.095
## [2,] 0.722 1.000 0.685 0.246 0.181
## [3,] 0.714 0.685 1.000 0.170 0.113
## [4,] 0.203 0.246 0.170 1.000 0.585
## [5,] 0.095 0.181 0.113 0.585 1.000
def
```

- Will use package lavaan for confirmatory analysis.
- Can use actual data or correlation matrix.
- Latter (a bit) more work, as we see.

Two or three steps

- Make sure correlation matrix (if needed) is handy.
- Specify factor model (from theory)
- Fit factor model: does it fit acceptably?

Specifying a factor model

- Jargon: thing you cannot observe called **latent variable**.
- Thing you can observe called manifest variable.
- Model predicts latent variables from manifest variables.
- Model with one factor including all the tests:

```
test.model.1 <- "ability=~para+sent+word+add+dots"</pre>
```

def

 and a model that we really believe, that there are two factors, a verbal and a mathematical:

```
test.model.2 <- "\nverbal=~para+sent+word\nmath=~add+dots"</pre>
```

def

Note the format: really all one line between single quotes, but putting

Lecture notes STAD29: Statistics for the Life and Social Sc 654/710

```
Confirmatory factor analysis}
```

Fitting a 1-factor model

ullet Need to specify model, correlation matrix, n like this:

```
fit1 <- cfa(test.model.1,
   sample.cov = km,
   sample.nobs = 145
)</pre>
```

def

fit1

##

Has summary, or briefer version like this:

```
## lavaan 0.6-3 ended normally after 16 iterations
```

```
##

```

Section 16

Multiway frequency tables

Packages

library(tidyverse)

Multi-way frequency analysis

A study of gender and eyewear-wearing finds the following frequencies:

Gender	Contacts	Glasses	None
Female	121	32	129
Male	42	37	85

- Is there association between eyewear and gender?
- Normally answer this with chisquare test (based on observed and expected frequencies from null hypothesis of no association).
- Two categorical variables and a frequency.
- We assess in way that generalizes to more categorical variables.

The data file

```
gender contacts glasses none female 121 32 129 male 42 37 85
```

- This is not tidy!
- Two variables are gender and *eyewear*, and those numbers all frequencies.

my url <- "http://www.utsc.utoronto.ca/~butler/d29/eyewear.tx

```
eyewear <- read_delim(my_url, " ")
eyewear</pre>
```

```
## # A tibble: 2 x 4

                             85
xt <- xtabs(frequency ~ gender + eyewear, data = eyes)</pre>
xt
```

Modelling

- Last table on previous page is "reconstituted" contingency table, for checking.
- Predict frequency from other factors and combos. glm with poisson family.

```
eyes.1 <- glm(frequency ~ gender * eyewear,
  data = eyes,
  family = "poisson"
)</pre>
```

def

Called log-linear model.

What can we get rid of?

```
drop1(eyes.1, test = "Chisq")
## Single term deletions
##
## Model:
## frequency ~ gender * eyewear
##
                 Df Deviance AIC LRT Pr(>Chi)
                       0.000 47.958
## <none>
## gender:eyewear 2 17.829 61.787 17.829 0.0001345 ***
## ---
## Signif. codes:
## 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
def }
```

Conclusions

- ullet drop1 says what we can remove at this step. Significant = must stay.
- Cannot remove anything.
- Frequency depends on gender-wear combination, cannot be simplified further.
- Gender and eyewear are associated.
- Stop here.

prop.table

```

Chest pain, being overweight and being a smoker

- In a hospital emergency department, 176 subjects who attended for acute chest pain took part in a study.
- Each subject had a normal or abnormal electrocardiogram reading (ECG), were overweight (as judged by BMI) or not, and were a smoker or not.
- How are these three variables related, or not?

The data

In modelling-friendly format:

ecg bmi smoke count abnormal overweight yes 47 abnormal overweight no 10 abnormal normalweight yes 8 abnormal normalweight no 6 normal overweight yes 25 normal overweight no 15 normal normalweight yes 35 normal normalweight no 30

First step

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/ecg.txt"
chest <- read_delim(my_url, " ")</pre>
chest.1 <- glm(count ~ ecg * bmi * smoke,
  data = chest,
  family = "poisson"
drop1(chest.1, test = "Chisq")
```

```
##
## Model:
## count ~ ecg * bmi * smoke
                Df Deviance AIC LRT Pr(>Chi)
##
                    0.0000 53.707
## <none>
## ecg:bmi:smoke 1 1.3885 53.096 1.3885 0.2387
```

That 3-way interaction comes out. STAD29: Statistics for the Life and Social Sc

Single term deletions

Removing the 3-way interaction

```
chest.2 <- update(chest.1, . ~ . - ecg:bmi:smoke)</pre>
drop1(chest.2, test = "Chisq")
## Single term deletions
##
## Model:
## count ~ ecg + bmi + smoke + ecg:bmi + ecg:smoke + bmi:smoke
            Df Deviance AIC LRT Pr(>Chi)
##
## <none> 1.3885 53.096
## ecg:bmi 1 29.0195 78.727 27.6310 1.468e-07 ***
```

Signif. codes:

ecg:smoke 1 4.8935 54.601 3.5050 0.06119 . ## bmi:smoke 1 4.4689 54.176 3.0803 0.07924 .

0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

At lpha=0.05, bmi:smoke comes out.

Lecture notes STAD29: Statistics for the Life and Social Sc

Removing bmi:smoke

```
chest.3 <- update(chest.2, . ~ . - bmi:smoke)</pre>
drop1(chest.3, test = "Chisq")
## Single term deletions
##
## Model:
## count ~ ecg + bmi + smoke + ecg:bmi + ecg:smoke
            Df Deviance ATC LRT Pr(>Chi)
##
## <none> 4.469 54.176
## ecg:bmi 1 36.562 84.270 32.094 1.469e-08 ***
## ecg:smoke 1 12.436 60.144 7.968 0.004762 **
## ---
## Signif. codes:
## 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
ecg:smoke has become significant. So we have to stop.
```

Understanding the final model

- Thinking of ecg as "response" that might depend on anything else.
- What is associated with ecg? Both bmi on its own and smoke on its own, but *not* the combination of both.
- ecg:bmi table:

```
xtabs(count ~ ecg + bmi, data = chest)
## bmi
```

```
## ecg normalweight overweight
## abnormal 14 57
## normal 65 40
```

 Most normal weight people have a normal ECG, but a majority of overweight people have an abnormal ECG. That is, knowing about BMI says something about likely ECG.

ecg:smoke

• ecg:smoke table:

```
xtabs(count ~ ecg + smoke, data = chest)
```

```
## smoke

## ecg no yes

## abnormal 16 55

## normal 45 60
```

- Most nonsmokers have a normal ECG, but smokers are about 50–50 normal and abnormal ECG.
- Don't look at smoke: bmi table since not significant.

Simpson's paradox: the airlines example

	Alaska Airlines		America West	
Airport	On time	Delayed	On time	Delayed
Los Angeles	497	62	694	117
Phoenix	221	12	4840	415
San Diego	212	20	383	65
San Francisco	503	102	320	129
Seattle	1841	305	201	61
Total	3274	501	6438	787

Use status as variable name for "on time/delayed".

- Alaska: 13.3% flights delayed (501/(3274 + 501)).
- America West: 10.9% (787/(6438 + 787)).
- America West more punctual, right?

Arranging the data

 Can only have single thing in columns, so we have to construct column names like this: \begin{small}

```
aa_ontime aa_delayed aw_ontime aw_delayed
airport
LosAngeles
             497
                            62
                                     694
                                                 117
Phoenix
             221
                            12
                                    4840
                                                 415
SanDiego
           212
                            20
                                     383
                                                  65
SanFrancisco 503
                           102
                                     320
                                                 129
                                                  61
Seattle
             1841
                          305
                                     201
\end{small}
```

 Some tidying gets us the right layout, with frequencies all in one column and the airline and delayed/on time status separated out:

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/airlines.tx
airlines <- read_table2(my_url)</pre>
```

STAD29: Statistics for the Life and Social Sc.

The data frame punctual

```

```

Proportions delayed by airline

Two-step process: get appropriate subtable:

```
xt <- xtabs(freq ~ airline + status, data = punctual)
xt</pre>
```

```
## airline delayed ontime
## aa 501 3274
## aw 787 6438
```

status

##

and then calculate appropriate proportions:

```
prop.table(xt, margin = 1)
```

```
## status

## airline delayed ontime

## aa 0.1327152 0.8672848

## aw 0.1089273 0.8910727
```

Proportion delayed by airport, for each airline

##

```
xt <- xtabs(freq ~ airline + status + airport, data = punctual
xp <- prop.table(xt, margin = c(1, 3))
ftable(xp,
   row.vars = c("airport", "airline"),
   col.vars = "status"
)</pre>
```

delayed

ontime

```
## airport

```

- What fraction of each airline's flights are to each airport.
- Most of Alaska Airlines' flights to Seattle and San Francisco.
 - Most of America West's flights to Phoenix.

The resolution

- Most of America West's flights to Phoenix, where it is easy to be on time.
- Most of Alaska Airlines' flights to San Francisco and Seattle, where it is difficult to be on time.
- Overall comparison looks bad for Alaska because of this.
- But, comparing like with like, if you compare each airline's performance to the same airport, Alaska does better.
- Aggregating over the very different airports was a (big) mistake: that was the cause of the Simpson's paradox.
- Alaska Airlines is *more* punctual when you do the proper comparison.

Ovarian cancer: a four-way table

- Retrospective study of ovarian cancer done in 1973.
- Information about 299 women operated on for ovarian cancer 10 years previously.
- Recorded:
- stage of cancer (early or advanced)
- type of operation (radical or limited)
- X-ray treatment received (yes or no)
- 10-year survival (yes or no)
- Survival looks like response (suggests logistic regression).
- Log-linear model finds any associations at all.

The data

after tidying:

```
stage operation xray survival freq
early radical no no 10
early radical no yes 41
early radical yes no 17
early radical yes yes 64
early limited no no 1
early limited no yes 13
early limited yes no 3
early limited yes yes 9
advanced radical no no 38
advanced radical no yes 6
advanced radical yes no 64
advanced radical yes yes 11
advanced limited no no 3
advanced limited no yes 1
advanced limited yes no 13
advanced limited yes yes 5
```

Stage 1

hopefully looking familiar by now:

A tibble: 16×5

```
my_url <- "http://www.utsc.utoronto.ca/~butler/d29/cancer.txt"
cancer <- read_delim(my_url, " ")
cancer %>% print(n = 6)
```

```

Comments

- stage:operation:xray has now become significant, so won't remove that.
- Shows value of removing terms one at a time.
- There are no higher-order interactions containing both xray and survival, so now we get to test (and remove) xray:survival.

Remove xray:survival

stage:survival

Lecture notes

Conclusions

- What matters is things associated with survival (survival is "response").
- Only significant such term is stage:survival:

```
xt <- xtabs(freq ~ stage + survival, data = cancer)
prop.table(xt, margin = 1)</pre>
```

```
## survival

## stage no yes

## advanced 0.8368794 0.1631206

## early 0.1962025 0.8037975
```

- Most people in early stage of cancer survived, and most people in advanced stage did not survive.
- This true regardless of type of operation or whether or not X-ray treatment was received. These things have no impact on survival.

What about that other interaction?

stage

```
xt <- xtabs(freq ~ operation + xray + stage, data = cancer)</pre>
ftable(prop.table(xt, margin = 3))
```

advanced

early

```
## operation xray
## limited
                         0.02836879 0.08860759
             no
                         0.12765957 0.07594937
##
             yes
## radical
                         0.31205674 0.32278481
             no
##
                         0.53191489 0.51265823
             yes
```

- Out of the people at each stage of cancer (since margin=3 and stage was listed 3rd).
- The association is between stage and xray only for those who had the limited operation.
- For those who had the radical operation, there was no association between stage and xray. STAD29: Statistics for the Life and Social Sc.

##

General procedure

- Start with "complete model" including all possible interactions.
- drop1 gives highest-order interaction(s) remaining, remove least non-significant.
- Repeat as necessary until everything significant.
- Look at subtables of significant interactions.
- Main effects not usually very interesting.
- Interactions with "response" usually of most interest: show association with response.
